## An Introductory Address

### ON MEDICAL STUDY.

*Delivered at the Opening of the Winter Session at St. George's Hospital on Oct. 1st, 1901.*

By P. W. LATHAM, M.A., M.D. CANTAB.,

FELLOW AND LATE SENIOR CENSOR OF THE ROYAL COLLEGE OF PHYSICIANS; LATE DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE; AND CONSULTING PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

GENTLEMEN,—When your excellent and honoured dean conveyed to me the request of the Medical Committee of St. George's Hospital that I should address to you some words of welcome and encouragement at the commencement of this winter session I received the invitation with great pleasure and satisfaction and I highly appreciate the compliment. These pleasurable feelings, however, are not unalloyed with anxiety, but if the suggestions and advice which I am about to offer should in any way lessen the difficulties which I know confront every medical student in determining his precise course of study or should help him to utilise his advantages here to their full extent my anxiety will be amply rewarded.

Never in the history of medicine has there been a time when so much interest was centred on its progress and its triumphs or when so much consideration as at present was given to the necessary training and education of those who, like yourselves, wish to take part in its practice. Medicine as a science and as an art has progressed during the last 50 years with enormous strides and is now progressing at an accelerated rate. Those who, like myself, can look back to a student's life half a century ago and have watched these advances may well be forgiven for envying a body of men whose work of life is beginning in the first year of this twentieth century. To consider one advance; imagine, if you can, what the practice of surgery would be now without the use of anaesthetics—and yet the discovery of the way in which to administer them successfully, a discovery which ranks as one of the greatest triumphs of science, was only made 55 years ago. The first operation ever rendered painless by ether was performed by Dr. Morton, a dentist of Boston, in the United States of America, on Sept. 30th, 1846. Nitrous oxide, or laughing gas, had been successfully employed for the same purpose two years previously. The gas was discovered by Priestley in 1776 and its composition was determined afterwards by Humphry Davy who in 1799, when 21 years of age, found out its intoxicating effect by experimenting upon himself. He also suggested its use in surgical operations, but it was 45 years before his suggestion was acted upon. Here are his remarkable words: "As nitrous oxide in its extensive operation seems capable of destroying physical pain it may probably be used with advantage during surgical operations in which no great effusion of blood takes place." On Dec. 10th, 1844, Horace Wells, a dentist of Hartford, Connecticut, after witnessing the intoxicating effects of the gas at a lecture on chemistry by G. O. Colton, invited the latter to administer the gas to him on the following day, and during the narcosis induced by it Dr. Riggs extracted one of his teeth. Wells then gave it to his patients, but the proper mode of administering it was unknown to him; he was deficient as an experimentalist and the results were uncertain. At one of the hospitals in Boston he completely failed to induce narcosis in a patient operated upon by Dr. Warren, and he was jeered at by the students and called a charlatan and a humbug. Morton, who had been an associate of Wells, made some attempts with this gas but abandoned it; and then experimented with sulphuric ether. He was not successful (so it is said) until Dr. Charles T. Jackson, an eminent chemist and geologist of Boston, pointed out to him the proper mode of inhaling it. The amount of credit due to each of these men for the discovery must for ever remain uncertain. Facts about which there is no uncertainty are that Morton narcotised E. H. Frost with it and extracted a tooth from him painlessly on Sept. 30th, 1846, and on Oct. 17th and 18th following, two operations were performed at Boston by Dr. Warren and Dr. Hayward, the one almost, the other

entirely, without any pain being felt. Now inhalations of ether had been employed for a long time before this for the relief of pain in phthisis, spasmodic asthma, chronic catarrh, dyspnoea, and whooping-cough. Dr. Richard Pearson in 1795 directed it to be inspired from a handkerchief wetted with it and held near the mouth and nose, and subsequent practitioners made use of it in the same way as an anti-spasmodic, so that for half a century practitioners were on the very threshold of the discovery of "anaesthesia" but missed it by not venturing far enough with the experiment. As Faraday said, "Who shall tell that new knowledge is not every day passing before our eyes and yet escaping our notice?" So it was with chloroform. This remedy was discovered about the end of 1831 and the beginning of 1832 almost simultaneously in America, France, and Germany. Guthrie of America and Soubiran of Paris obtained it from chlorinated lime and alcohol, and Liebig from chloral, which he had just then discovered. It was employed in America for the same purposes as ether, inhalations being used to relieve difficult respiration. Dr. Black of Bolton recommended its use internally in 1833 in spasmodic asthma, and about the beginning of 1839 it was used medicinally in Liverpool by Mr. Waldie and Dr. Formby. In 1847 Dr. (afterwards Sir James) Simpson was endeavouring by experiments upon himself and his friends to discover some anaesthetic less inflammable than ether and free from its other drawbacks, and Waldie suggested to him in November of that year to try chloroform. The experiment was successful. Those who inhaled it grew exhilarated and several became insensible. Simpson renewed his experiments and subsequently completely anaesthetised a patient on whom Professor Miller operated for a necrosed radius. With regard to the discovery of anaesthesia Dr. Stillé says: "If the most valuable discoveries in the natural sciences, and above all in medicine, were usually the result of logical inferences from experience, a means of producing insensibility to pain would undoubtedly have been one of the first fruits of man's ingenuity and research. But such discoveries are very differently made. All, or nearly all, of them are the results of an apparently fortuitous concurrence of circumstances such as human wit alone could never have created." And again: "It is a singular coincidence that chloroform and ether should both have required for their introduction as anaesthetics the coöperation of a scientific and a practical man. What Dr. Jackson was to Dr. Morton in America, Dr. Waldie the chemist was to Dr. Simpson in Great Britain. Practical genius is not less essential than scientific genius to the advancement of society." I suggest that it was the want of the coöperation of the practical man with the brilliant scientist of 21 years of age that delayed the fulfilment of Humphry Davy's prophecy. The practical man appeared nearly 50 years later in the person of Wells, but it was not until after another 20 years that the efficiency of the gas was fully recognised in England. The first tooth extracted under its influence at the Dental Hospital in London was on March 31st, 1868. Since then tens of thousands have had reason to be thankful to Priestley and to Humphry Davy for their "laughing gas." And so, Gentlemen, I come to my text: While you struggle to be scientific do not forget to be practical. I differ altogether from the definition given by a great Conservative leader of a practical man as one "who practises the errors of his predecessors." The practical man, in my opinion, is one who utilises the experience of his predecessors, neglects no opportunity of increasing his own knowledge, and is open to receive and to utilise knowledge from every quarter. He is an observer of nature and a careful watcher of natural processes and operations in all their varying forms. The practical man administers his remedy because he knows that under certain conditions it will cure or relieve his patient, but if he has an inquiring mind he goes further—he seeks to define those conditions and to find out what is the active element in his remedy, and for the latter purpose he has often to search a long time, even though assisted by the most scientific of assessors. The practical physician for three centuries successfully used burnt sponge and seaweed in the treatment of goitre before Courtois, a soda-water manufacturer, discovered iodine in 1811. Seven years later this substance was found by Straub of Hofwyl in sponges and other substances, and then Coindet of Geneva, suspecting that their curative property was due to the iodine, at once put his conjecture to the test of experiment and met with astonishing success. After 80 years' use of the remedy we still want a scientific explanation of its action. We are told that it is an "absorbent" and that its physiological

action is to "alter nutrition." These are merely words. The practical man says that, properly administered, it will cure certain forms of goitre and other morbid conditions—he knows the "go" of the thing; he would be glad to know "how it goes." The same may be said of many other remedies. Chloral, the substance from which Liebig obtained chloroform in 1832, was only introduced into general use as a remedy in 1869 by Liebreich. The practical man knows how to use it advantageously, but if he asks why it causes sleep all he is told is that, like opium, it possesses the "vis dormitiva." The notion which led to the use of this remedy—namely, that in the alkaline blood it was converted into chloroform and a formate—is now held to be erroneous, but the value of the medicine and the merit of its proposer are not thereby diminished.

The history of bromide of potassium shows how the practical physician—i.e., the clinical observer—may precede and out-distance the scientific investigator. Bromine was discovered by Balard, an apothecary of Montpellier, in 1826, and being chemically similar to iodine its potassium salt was at once tried in cases of scrofula, syphilis, and glandular swellings, diseases in which iodine had proved useful. No improvement, however, took place in these disorders under its use, but its effects in large doses on the brain were noticed. Its reported action as an anaphrodisiac led Sir Charles Locock in 1853 to use it with marked success in hysteria and hysterical epilepsy, but it was rarely employed by others until 1858, when Dr. C. B. Radcliffe tried it for the various forms of epilepsy and epileptiform disorders and declared that it was the remedy in these cases upon which most dependence could be placed. This was confirmed by Dr. Hughlings Jackson and by Brown-Séquard. Dr. Russell Reynolds says: "It is the one medicine which has, so far as I know, proved of real service in the treatment of epilepsy." Scientific investigation as to its effects on animals produced results which were confused and contradictory. Professor Binz says: "This was due to various causes. In the experiments the effects of the potassium constituent were either not taken into account or the results were entirely attributed to it. The experiments were made on *animals* which in comparison with man are in general much less sensitive to the action of narcotics, at least so far as the cerebral hemispheres are concerned; the experiments, moreover, were made on *healthy* animals, without reflecting that a healthy nervous system may probably be less influenced by any sedative remedy than one which is morbidly excited; and finally in many cases the dose employed in the experiments was far too small. A rather lengthy series of experiments ..... showed how facts that had been established in the diseased applied to the healthy and furnished an explanation of some of the peculiarities which had been observed in experiments on animals."

The history of other remedies could easily be cited to illustrate my contention that the practical observant physician is an important, if not the most important, factor at the present day in the progress of medical knowledge, but I should weary you. I cannot, however, resist pointing out that the present mode of treating tuberculous patients is not modern and that the open-air treatment of phthisis did not originate and was not "made in Germany." In a work written nearly 50 years ago Dr. J. Hughes Bennett says, first with regard to diet, that it should be "one of a nutritious kind, consisting of a good proportion of animal food abounding in fat. .... No effort should be spared to overcome the obstacles which prevent food of sufficient quality and quantity from being digested. .... The strongest stimulus to the appetite is exercise." The extent to which this "should be carried ought always to be short of anything like fatigue. .... Going out in the open air at least should be insisted on, as sitting in a garden or open place is much better than remaining in a room, the person, of course, being well clothed according to the season of the year. .... The necessity of proper ventilation in the sitting and sleeping-rooms ..... is of essential importance. I agree with Dr. McCormack of Belfast in thinking that the best ventilator is the sash window let down for an inch or so from the top, and that this with an open fire sufficiently ventilates the apartment; ..... the air which enters the lungs should be as pure as possible and constantly renewed." And then he makes a suggestion which even now might be advantageously acted upon. For those who financially are unable to search out a favourable climate on the continent "what is required is the means of exercise in the open air, whether on foot, on horseback, or in a carriage, where the patient is protected from cold winds and where the mind can be amused by

pleasant sights and cheerful conversation. Such is the case in all those favoured localities considered best for consumptive people, and some such advantages might be derived from the Crystal Palace at Sydenham, near London. Delicate individuals can be transported there by means of a close carriage in the worst seasons without difficulty and on entering it could breathe for hours a pure balmy air, meet their friends, take exercise in various ways, read, work, and otherwise amuse themselves. Such an outdoor means of recreation, combined with careful hygienic regulations at home, will go far to remove many of the difficulties which we have to encounter in the ordinary treatment of consumption."<sup>1</sup> This I conceive is the "open-air treatment" in a nutshell—proper food, exercise short of fatigue, and abundance of fresh air. I have some satisfaction in thinking that at an early period I adopted Dr. Bennett's views and that in 1864 in my first contribution to medical literature<sup>2</sup> I endeavoured to show that with these three factors we had the means best adapted to prevent or arrest the progress of the disease.

Gentlemen, I ask you to fit yourselves to become "practical" physicians and surgeons in the sense in which I have used the term. How are you to do so? The great majority of those whom I am addressing have deliberately chosen the medical profession in order to live by it and, with an honourable desire to support yourselves, you wish to exercise its practical duties as soon as possible. On this account you should be shown the nearest and the easiest way to attain your end. You are here, not to become philosophers or scientists or physiologists, but are students seeking how you may prolong life or cure disease and endeavouring to acquire such knowledge as will enable you to undertake the serious duties of a medical practitioner with credit to yourselves and advantage to the public. Keep this important fact firmly in your mind. A sound knowledge of what is absolutely essential is what should be conveyed to you and what should be rigidly exacted from you in the examinations, and nothing more—and with ordinary diligence, with continuous work, and with reasonable intelligence that sound knowledge can be attained within the period which has been assigned for it by the General Medical Council and by the various corporations. These authorities have decreed that the first two years of your student life should be devoted to the study of chemistry and physics, biology, anatomy, and physiology, and wisely and well have these subjects and their order been suggested. At the end of your first year you are expected to pass the examinations in physics, chemistry, and biology, and at the end of the second year your examination in anatomy and physiology, and with steady work you can do this. A great deal, however, will depend upon your previous school training, whether, in fact, you have been taught "how to learn"—how to concentrate your energies on the work immediately before you, and whether your reasoning powers have been carefully developed and educated and your judgment strengthened. This is the training you ought to have had, and with such a training you will gain infinitely more knowledge in a given time and be able to apply your knowledge far better than the man who has not gone through it. Chemistry is the science of experiment, anatomy is the science of observation, and in physiology are combined pure observation and experimental research; but in studying these sciences, unless you have been trying to draw correct inferences from your observations and experiments, you will simply remain the mere collector of facts without the power to apply them. As a recent writer in the *Times* says: "Men of science are composed of two widely different classes—a very small minority who discover laws and a considerable majority who only discover facts. The two classes are far as the poles asunder, but they are constantly confounded together by the vulgar who are even more likely to be impressed by the work of the latter class as more within their comprehension than they are by that of the former. The worker at facts alone may well be little more than Johnson's definition of a lexicographer, 'a harmless drudge,' but he has been taught correct methods of working, and will pursue to the end an investigation the clue to which has been put into his hand. When Pasteur had once satisfied himself that certain forms of disease were constantly associated with the presence of minute organisms foreign to the natural state of the diseased body, his far-seeing intellect

<sup>1</sup> The Pathology and Treatment of Pulmonary Consumption, by John Hughes Bennett, M.D., F.R.S.E., second edition, 1839, p. 135.

<sup>2</sup> On the Early Symptoms of Phthisis and the Means Best Adapted to Prevent or Arrest its Development. Cambridge: Deighton, Bell, and Co., 1864.

led him at once to the generalisation that the organisms were the cause of the disease, and that all diseases of analogous type must be caused in a similar manner. He had excogitated a law which even in its immediate applications was of incomparable importance to the human race. His followers, having learned correct methods of investigation, and improving these under the guidance of experience as they worked, set themselves to find and identify the organisms of this disease and of that, of diphtheria, of cholera, or of typhoid; and so, in one sense, they were rightly spoken of as the 'discoverers' of the organisms in question. But they had discovered only what they were sure to find; and their discoveries differ from those of their master as the discovery of a mathematical formula differs from those of the work of the calculator who employs it." I therefore ask you in your study of chemistry, anatomy, and physiology to limit and narrow the ground to what is absolutely essential, but to cover the whole of that narrow limit and to master every inch of the ground. Make your foundations secure as far as you go. Later, when you have become practitioners of medicine, you will realise how advantageous it may be to enlarge your knowledge, not only for your professional work but as a means of relaxation, and if your foundation is sound the additions can easily be made. I can readily imagine that the wonderful revelations of physiology and the brilliant experiments and results achieved by the chemist will so charm and interest you that you may be induced to devote all your energy to one or other of these sciences and forsake the study of medicine. If you resist the temptation I will promise you that in your later studies and in the application of them in the practice of your profession you will find an interest and a fascination in your work equal—nay, transcending—any that can be called forth from any chemical or physiological experiments, for your investigations will then be upon human beings and you will be engaged in the great experiments of appeasing pain, of repairing injuries, of controlling disease, and of averting death, and to attain to success in such experiments is well worth all the care and skill and experience that you can bring to bear upon them.

To the vast majority of students, wherever their studies may be pursued, it is disastrous to spend more than two years over the preliminary scientific studies. That this is so I can clearly demonstrate by the results obtained at the university with which I am most familiar—namely, Cambridge. At that university chemistry, anatomy, and physiology are recognised as subjects qualifying for graduation in pure science, and those who successfully pass an examination in them in the Natural Sciences Tripos are entitled to the degree of Bachelor of Arts. With this inducement before them the medical students at Cambridge, with very few exceptions, proceed to a degree in arts by the Natural Sciences Tripos, and devote three entire years to the study of chemistry and physics, anatomy and physiology, and so spend a large amount of time over many parts of chemistry, physiology, and so on, which have no direct bearing on the curing of disease. Unfortunately, it is decreed that however complete and extensive may be the acquaintance which a candidate shows with any of these subjects in the Tripos examination it does not exempt him from re-examination in the same subjects for the medical degrees, a pretty clear admission by the medical authorities that the scientific training for the Tripos is something outside and differing from the training necessary for the student of medicine. What is the practical result? 50 per cent. of those registered as medical students at Cambridge never proceed to the degree of Bachelor of Medicine. By referring to the Medical Students' Register issued by the General Medical Council you will find that the students who were registered as commencing medical study at Cambridge in the six years from 1888 to 1893 inclusive numbered 630, distributed as follows:—

	Number registered after the previous examination.	After the degree of Bachelor of Arts.	Totals.
In 1888 ... ..	85	10	95
" 1889 ... ..	92	5	97
" 1890 ... ..	97	3	100
" 1891 ... ..	94	9	103
" 1892 ... ..	106	4	109
" 1893 ... ..	116	10	126

Five years of medical study are required, but I find that very few indeed at Cambridge obtain the degree of Bachelor of Medicine in less than seven years from registration. Some take eight or more. Taking seven years, then, as the mean time, I find from the Cambridge Calendar that in the six years from 1895 to 1900 inclusive the number who proceeded to the degree of Bachelor of Medicine was in 1895, 52; in 1896, 52; in 1897, 54; in 1898, 55; in 1899, 54; and in 1900, 49—a total of 316. That is to say, that whilst 630 students were registered as commencing medical study in Cambridge in the years 1888 to 1893, in the years 1895 to 1900 only 316 proceeded to the degree of Bachelor of Medicine, leaving a deficiency or wreckage of 314, or 50 per cent. It would be very interesting to know what has become of these 314. No doubt a certain number, allured by the attractions of science, have given up a medical career, and in the future will be heard of as distinguished chemists, anatomists, or physiologists, and some may have obtained their qualifications elsewhere; but what about the rest? I fear that the three years' study of science for its own sake or for the attainment thereby of an arts degree, without any reference to the special requirements of the medical curriculum, had an unfortunate effect in determining the course of those men who abandoned the wish to obtain a medical degree at Cambridge. I think that this illustrates very forcibly what I was trying to impress upon you, that if you are to become qualified practitioners within five years it is of the first importance that your study of these preliminary sciences should be limited to two years and that you should be required to know only that which an ordinary individual can learn in the time, and that which is absolutely essential—nothing more. Shall I surprise you if I say, Do not strive in the limited time before you to know too much, to cram in too much science, but learn to apply what you do know. As has been well observed, there are men "who never have done and never can do anything because they know too much, whilst others possessing comparatively small knowledge are so dextrous in its use that they have ridden over the heads of others far their superiors in acquirements."

I now turn to those who having passed the examinations in anatomy and physiology must, in the next place, learn to apply their knowledge and are preparing for the final stage—the examinations in medicine, surgery, and midwifery. Henceforth work in the hospital wards must engross the greater part of your time. Having acquired a knowledge of what is essential as regards healthy function and healthy structure, you have now to investigate morbid processes, to learn how to detect these morbid conditions in the living subject, to watch their origin and progress and termination, to see how they differ from the healthy processes, and not only must you continue to accumulate your facts, but your sense of sight and touch and hearing must be educated and cultivated. What is obvious to an experienced observer may be overlooked by the student; the sounds which are readily detected by the trained ear are inaudible to the untrained; the cultivated touch detects variations which are imperceptible to others. These senses can only be educated by practice. The numerous phenomena and the various physical signs connected with diseases of the chest, for instance, can only be recognised after prolonged and careful study of a large number of cases. You must look and hear and feel for yourselves, and having made your observations you must think and reason upon them and must learn accurately to interpret their meaning and to draw correct conclusions from them. This kind of knowledge is only to be acquired at the bedside or in the out-patient room from practical demonstrations and your own personal investigations. Your course is, as hitherto, largely controlled by the requirements of the licensing bodies, and lectures and demonstrations have to be attended and practical work has to be accomplished according to a certain defined plan which will be duly pointed out to you by your teachers.

The medical student is, unfortunately, a much-lectured individual, and I think I shall enlist the support both of teachers and of students when I express a hope that the time is not far distant when systematic lectures on pathology, pharmacology, medicine and surgery, and mental diseases will be discontinued and students thereby enabled to devote more attention to practical work and demonstrations. Formal lectures on these subjects are the inheritance of an ancient system, the relics of a time when books were scarce, but the system lingers on and apparently will "die hard." Eight-and-twenty years ago I had the privilege accorded to me by the then Editor of THE LANCET of

advocating in that journal<sup>3</sup> two important changes in the interest, as I conceived it, of medical students. These were, first, the promulgation of schedules limiting the range of the examination in each subject, the questions to be strictly kept within this range, and the examination therein to be searching and complete; and secondly, the abolition of certificates of attendance on lectures with the provision that when a student presented himself for public examination he should bring with him certificates from his teachers of having gained sufficient knowledge to justify him in so doing. These views were endorsed by the Editor of THE LANCET<sup>4</sup> and by Professor Alexander Harvey<sup>5</sup> of Aberdeen. The following year at the meeting of the General Medical Council in June, 1874, the two following recommendations were adopted:—

That the Council recommend that in the case of certificates presented before admission to the examinations of the several licensing bodies each should include a statement from the teacher or teachers that the candidate had satisfactorily attended examinations from time to time held on the subject of study to which the certificate relates.

That it is desirable that, in the examinations on several of the subjects of the curriculum—such, for example, as botany, zoology, chemistry, and materia medica—the area of the examination should be limited and defined.

Here were two points gained. In the following year, however, the General Medical Council spent most of an afternoon in discussing the merits of the recommendations which they had passed a year before. The discussion ended simply with a resolution instructing the registrar to write and inquire what the licensing bodies thought of the recommendations and how far they had been carried into effect. The discussion, however, was not wholly fruitless. In the first place, it elicited from the then representative upon the Council of Oxford University, Dr. H. D. Rolleston, an exceedingly clear and decided expression of his views on medical training. He went further than I had ventured to do. He maintained that the examiners should have no extraneous information from teachers or elsewhere, but was strongly in favour of free trade in teaching and learning—i.e., of leaving every man to his own will as to the time and place in which to acquire his knowledge: a proper and sufficient examination being the sole test whether the knowledge had been acquired. In Dr. Rolleston's opinion all that licensing bodies had to do was to find out for themselves whether students possess certain knowledge and aptitudes, and that examiners had no business to concern themselves with details of the process by which teachers give and students receive that knowledge. Sir William Gull took the same view, saying that if a candidate was found to possess adequate knowledge it was really of no consequence how he came by it. In the second place, that discussion by the General Medical Council led to schedules being framed by some of the examining bodies and class examinations instituted in the schools. Students who are preparing for the Conjoint Board examination have now the schedules to guide them, and in the school of St. George's Hospital there are highly qualified teachers appointed to direct and test and examine you from time to time in the progress of your studies, but you are still compelled to attend systematic lectures and to produce certificates of attendance on them. Dr. Rolleston's free trade in teaching and learning is still, except in his own university, a thing of the future. Influenced, no doubt, by Dr. Rolleston's spirit, certificates of attendance on lectures, on medicine, surgery, pathology, and pharmacology, are not required at Oxford; what are required are certificates of having performed certain practical work. Nowhere are medical students better trained in the preliminary studies than in that university, and the regulations both for degrees in medicine and for the honour school of natural science are models which other universities and licensing bodies might copy with advantage.

Leaving, then, the subject of systematic lectures I will say a word or two about your clinical lectures and practical demonstrations. For these I hope you will have a capacious appetite, followed by a vigorous digestion. Take in all you can assimilate, but whatever you attempt let it be done thoroughly. In commencing hospital work you will perhaps learn more in the out-patient department than in the wards. The junior teachers have more time generally for tutorial work than their seniors and here you will be instructed in, and have the best opportunities of learning, the elementary work—of learning, that is, how, by general symptoms and

physical signs, to diagnose a healthy organ from one that is diseased. The out-patients can bear the examination of their various organs with much less inconvenience than the in-patients. The latter generally are more seriously ill than the out-patients, and I think they should never be examined except by those who have already acquired some skill and dexterity in the performance. At the same time do not neglect the wards. Go there and quietly observe the cases, but make no notes except mental ones. Your business at first is to observe, not to record, and after a time you will learn what it is you should record and how you should arrange it for future use and reference. Study the physiognomy of disease—you will often find it characteristic; note the position of the patient, the way he breathes; feel his pulse and educate your touch to discriminate its qualities; and look at his tongue and make any observations you can without inconveniencing the patient. Then in three or four months, when you have become familiar with some of the leading symptoms of disease and have learned how it is to be detected and how one disease is to be distinguished from another, you can begin to take notes. You will need to learn now what changes of structure take place in the diseased organs, how the morbid conditions are to be recognised, and how far they explain the phenomena which characterise the disease. You will further wish to know how the disease is to be fought, how death is to be averted, what effect remedies have upon the disease, why the action of the remedy seems to differ in one case from another, and so you turn your attention to pathology, pharmacology, and therapeutics, and thus, at last, you blend into one harmonious whole the study of the pathology and treatment of disease. This is your life's work, and, begun now, must be continued throughout the whole period of your professional career. Begin it well—watch the patients carefully throughout the disease; take accurate notes, but only of a few cases, and those of well-marked disease, at first; discuss and compare the cases with your fellow-students; see how far your account agrees or not with what is stated in the text-book; satisfy yourself as to the healthiness or unsoundness of the other organs of the body besides the one prominently implicated. Do this habitually and systematically; you will find it of great service in after years. The practice will soon become easy, afterwards almost automatic. Study one class of diseases at first from beginning to end, and as you become familiar with their symptoms then proceed to another class. Trained in this way, cultivating your powers of observation and of diagnosis both in medical and surgical cases, you will fit yourselves to hold with great profit and advantage the various clinical appointments in the hospital and you will be enabled to present yourselves for your final examinations not only without fear as to the result but with credit to your teachers.

Finally, having reached this goal and attained to the dignity of qualified practitioners, you come to the "parting of the ways," each one taking his special path in life. Some will have the good fortune to obtain the resident appointments in this hospital, with all the responsibilities and advantages attached thereto. Others, perhaps, will offer their services as assistant to some medical practitioner. I strongly advise such a course either in London or the country, especially if in either case you can have the opportunity of spending even a few hours each week in the wards of a general or special hospital. There is a great deal to be learned in many ways in the management of a private practice which I need not specify. In years gone by this was acquired during an apprenticeship before commencing hospital practice and it was acquired so insensibly that it appeared easy and natural, but it requires training and it requires time, it is beyond the hospital programme, and it can best be acquired, as I have suggested, by working under the supervision of one who is actively engaged in private practice.

Other students, again, who have the means may wish to devote their energies to the elucidation of some special problem in pathology or therapeutics. The field is enticing and full of promise, for we are on the eve, I believe, of great discoveries, chiefly, if not entirely, through the aid of organic chemistry. For this purpose and at this stage of your career your time will be well spent in obtaining a thorough insight and a manipulative skill in the methods of this branch of science. Every day is making it clearer that organic chemistry must play the chief part in the advancement of medical science and that we must look to it more and more to explain the various physiological, pathological, and therapeutic processes about which at present we can only

<sup>4</sup> THE LANCET, Oct. 25th, 1873, p. 602.

<sup>5</sup> THE LANCET, Nov. 29th (p. 765) and Dec. 6th (p. 801), 1873.

vaguely guess. What, for instance, is the chemical nature of the proteids? Of what organic constituents are they made up? We know some of the constituents which can be derived from them, but in what form do these substances exist in the proteid body itself? What a flood of light would be shed on all our investigations if those questions could be answered and if we knew what molecular changes were induced in proteid by physical or chemical agents. These questions seem to be at the root of all physiological knowledge, and until they are solved we must still unwillingly grope in the dark.

Our indebtedness to the bacteriologist is already incalculable, but bacteriological science is only in its infancy. We know a good deal about the bacilli and a little about the poisons they produce and the disorders with which they are associated. We know, too, that in some disorders—diphtheria, for instance—if antitoxin be used early enough the disorder can be absolutely held in check, can be cured, but sometimes (so the bacteriologists tell us) the bacilli may remain attenuated or scotched—not killed—in the immunised patient and ready, on finding suitable soil in another host, to develop their virulence and their poisonous products. Organic chemistry must, and in time will, tell us what is exactly the composition and constitution of these toxins, albumoses, antitoxins, &c., and how they may be artificially synthesised in the laboratory. The vegetable alkaloids, quinine, morphine, atropine, and others, have been isolated within the last century and the syntheses of citric acid and indigo have been effected from their elements. The isolation of the animal alkaloids may be more difficult but it will be accomplished. Some have already been obtained, others will follow; the isolation of the antitoxins will be the next chemical triumph, and then will come the synthetical production of these life-saving substances.

But I hear someone exclaim, "Stamp out infectious disease by isolating every affected individual and by quarantining every person who has been exposed to the possibility of infection, and there will be no need for chemical triumphs, no need for antitoxins, for the specific malignant bacillus will have ceased to exist." There is some truth in the assertion. Outbreaks of infectious disease have been localised and completely stamped out in this way, and what has been done on a small scale can, it may be argued, be done on a large. But is it so? If every infectious disease were absolutely eradicated could they not rise again *de novo*? Is it impossible for the beneficent micro-organisms which swarm within us and around us to acquire virulent properties under certain conditions of food, temperature, and environment? There is abundant evidence that the virulence of parasitic or pathogenic organisms can be so modified and attenuated that they cease to be poisonous, but why this attenuation takes place is not clearly explained. Under special treatment, however, the organisms can regain their virulence. If this is the case it seems incredible that organisms of similar structure, though apparently harmless, cannot be cultivated in some way or other so as to become pathogenic—that the typhoid bacillus, for instance, should not be the debased offspring of some such organism as the bacillus coli communis, or the bacillus anthracis of some such organism as the bacillus subtilis. If these virulent and pathogenic organisms were really all included in Eve's apple they must have been there only in an attenuated form and required to pass through a generation or two of fallen humanity in order to develop their virulence. But I do not hold to that view; I believe that from the neglect of ordinary sanitary measures innocuous or beneficent micro-organisms may become virulent and that infectious diseases may arise *de novo*. Of what beneficent organism the tubercle bacillus is the degenerate offspring I cannot tell, but we believe now that after it has commenced its ravages on the human frame we can by the "open-air treatment" attenuate or kill the bacillus and arrest or, as some say, cure the disease. Would it not be better to try the treatment a little earlier, to say to the healthy, "Live regular and moral lives, take sufficient food and breathe pure dry air"? If they have the sense and the means they will do this habitually and so escape sanatorium life. But how about the poor? Can those who live in close alleys, in insanitary cottages, in crowded sleeping-rooms, and on insufficient food escape the scourge? These are the conditions under which tubercle bacilli develop, nay, under which, as I believe, they originate. Open up the narrow streets, remedy defective drainage, apply the open-air

treatment to those who are still healthy, and fewer sanatoria will be necessary. More than a quarter of a century ago, simply by improving the drainage and thus drying the soil the mortality from consumption at Salisbury was lowered by 49 per cent., at Ely by 47 per cent., and at Rugby by 43 per cent., and this was the result of utilising only one of the factors I have enumerated. The great problem is to determine from what organisms these pathogenic microbes arise and under what conditions they acquire their virulence. The "development of species" of these benign and malignant microbes must, as in other parts of the animal and vegetable kingdoms, be subject to some laws. What are the laws? I venture to prophesy that they will be formulated before many years are over. May it be the good fortune of some of those whom I have now the privilege of addressing to verify the prophecy, to discover the laws, and to solve the problem.

## Introductory Address

ON

### LIFE AND CHARACTER.

*Delivered at Charing Cross Hospital Medical School at the Opening of the Winter Session on Oct. 2nd, 1901.*

By JOHN W. TAYLOR, M.D., M.Sc.,  
F.R.C.S. Eng.,

PROFESSOR OF GYNECOLOGY, BIRMINGHAM UNIVERSITY.

GENTLEMEN,—It seems but a few years since I sat in the old lecture theatre across the road and listened to my first introductory address from the late Dr. Julius Pollock. It is, however, some 30 years or more, and as I look back over all the road that I have traversed since that date and think of the journey, the men with whom I have travelled, the inns at which I have rested, and then look forward and see the long white road still stretching upward—for

"The road winds up-hill all the way,  
Yes, to the very end"—

the main thoughts which come to my mind are those connected with the mystery of this life and the unfinished lessons to be learnt from its experience. All the manifold teachings of science tend to magnify one's conception of its greatness. Not without reason are we told that—

"Planets have toiled, forgotten suns have burned  
That we may live,"

and limitless as is the Past out of which we came, none the less limitless is the Future into which we go.

Heirs, then, of all that limitless past, born to take part—and some worthy part—in that portion of the great unfolding peculiar to your age, I would have you take no mean view of your mission and your destiny, feeling assured that however highly you regard it you will still fail of the reality. Whatever may await us in the future, this much is given us here and now—the gift of the present life; a fortune which may be squandered or spent wisely; a trust for which, in one way or another, we may have to account, and that to the uttermost farthing. Therefore, it is not a thing to be treated too lightly. Its little ironies may well be subject for humour and amusement, but it is too great a thing to be sacrificed in the pursuit of pleasure; and, on the other hand, it is hardly so grievous that a man need go to the cloister or the desert in order to escape its many contaminations. As de Tocqueville has wisely said: "Life is not a pleasure or a sorrow but a grave business, which has been entrusted to our charge, and which we have to carry through to an honourable end." "A grave business"—a business that has its dangers and hardships, its times of adversity, in which we have to

"Breast the blows of circumstance  
And grapple with our evil star."

"A grave business," which has its times of triumph when the goal of years has been achieved and a light which is of neither sea nor land floods the long white road with radiance. A business "entrusted to our charge," and therefore one that we cannot shirk and one that we cannot lay down until the Bearer of the Great Invitation crosses our threshold. So to every man, without question or choice, comes the fortune and

responsibility of life; so to every man comes the subsequent question and choice. "What will you do with it?"

To some of you this day of the introductory address will mark (as it did to me) the final decision, the acceptance of a special career or destiny, the definite entry on a life-work. Some events in our lives appear to have only a temporary significance; some have an extended influence over months or years; others, again, are essentially for ever. To this class the step you have taken to-day belongs. Little as you may now realise it there will probably be no returning. Of all my fellow-students in the old days I can only think of one who really changed his profession, so that henceforward all your life will be fashioned and coloured by the profession you have chosen, and the great Mistress of Medicine in whose service you have enlisted will demand your constant and unswerving allegiance. The choice is a great one, but it need not weigh on you too heavily. So wide, so increasingly vast, is the realm of medicine that in her service every order of mind can find congenial work. In anatomy and physiology, with all their connected studies, in bacteriology, in practical medicine and surgery, in sanitary science, in the medical departments of the army and navy (so well and faithfully served by many Charing Cross men), and in the various legitimate departments of special practice, there is ample scope for various shades of taste and acquirement. Indeed, to most men the manner of following the career they have chosen is of far greater importance than the making of the choice. Perhaps you may remember how this idea is expressed by my fellow-townsmen, Mr. Shorthouse, in his novel of "John Inglesant." One of his characters applies it—and to the extremest limits—in his review of the different sides of political and religious life which presented themselves for choice to the hero of the book. "Hereafter," he says, "it will be of little importance which of these new names, Cavalier or Roundhead, you are called by, whether you turn Papist or Puritan, Jesuit or Jansenist, but it will matter very much whether you acted as became a man and did not flinch ignobly at the moment of trial. Choose your part from the instinct of your order, from your birth, or from habit, or what not; but having chosen it follow it to the end. Stand by your party or your order, and especially in the hour of trial or danger be sure you never falter; for be certain of this, that no misery can be equal to that which a man feels who is conscious that he has proved unequal to his part, who has deserted the post his captain set him, and who, when men said, 'Such and such an one is there on guard, there is no need to take further heed,' has left his watch and quailed before the foe, to the loss, perhaps the total ruin, of the cause he had made his choice." I think, with still greater justice, that we might paraphrase this and say: It will hereafter be of comparatively little importance whether you are a soldier or a sailor, a clergyman, or a medical man, or a lawyer; but it will matter very much whether you acted as became a man called to the duties and responsibilities of the life you have chosen. Every now and then a man is born with overmastering talent for some special work and is unhappy and "sterile" until that work is found, but to most men of honest purpose and diligent habit every calling will afford opportunity for advancement and for honour. A good man comes to the front in any work he undertakes according to his industry and opportunity, and nowhere, I suppose, is opportunity richer than in the walk you have chosen.

But the service of your mistress must be whole-hearted and generous. What gifts have you to bring with you? A healthy and well-trained body, a well-educated mind, a high moral purpose—all these she claims for really successful service; and if to this can be added the beginning of some wider culture in literature, in art, and in music, the better and richer will be that service. I am not one of those who think that the education of medical students and practitioners should be restricted as far as possible to scientific subjects only. There are undoubtedly some men of fine but limited capacity who do well to narrow their energies and fix these solely on the subjects of their special study, but to men of wider taste and sympathies this is not only unnecessary but impossible. Accessory studies, however, should be strictly and proportionately subservient to one's life-work and the special study necessary for its mastery. If this be assured, the wider the culture the finer and more delicate will be the perception of various shades of difference between health and disease and between man and man—the better

will the observer recognise and describe points that have been missed by those before him, the greater will be his power to grasp and to investigate the larger problems of medicine—those involving many issues.

The ability to express oneself in clear and vigorous language is rarely gained unless one's study of literature has been considerably wider than that afforded by professional writing only. The power to portray both the normal and abnormal by sketches in pencil or colour (so great an advantage in all records of work and in teaching) must be prefaced by some artistic education and practice; and accurate perception of pitch in sound (so much needed in medical diagnosis) comes best by musical training. In addition to these some knowledge of modern languages, and especially of German, is almost a necessity if one is to keep pace with the days in which we live and the work that is done in them; while to those who may hereafter devote themselves to the practice of surgery some knowledge of handicraft, of the bench and lathe, and the practice of any neat handiwork that presents itself will be of decided service. This use of the hands, however, will almost always be spontaneously acquired by anyone who has a surgeon's instinct.

These, then, are some of the good gifts which tend to fit the possessor for the study and practice of medicine and which, if you possess them, you lay to-day upon her altar. Hitherto you have sought them, perhaps, for your own pleasure and glory. Henceforth you hold them as more or less subservient to your life-work and as helping to fit you for the service you have undertaken.

If I look back on my own experience of life and of its testing power, how do these greater qualities of body, of intellect, and of morals stand out in life's struggle? What is their relative value, and what instances can I recall of gain or loss resulting from their presence or their absence? One of my old fellow-students, an athlete and good cricketer, finding as a young practitioner his time unoccupied, scorned to pretend otherwise, spent much of his long summer days in the cricket-field, and, in his own words, "cricketed himself into the best county practice of the district." Doubtless he had many other solid qualities behind his cricket scores, but this was the door or gate which opened for him the pathway to success. In many other ways, too numerous to mention, the value of a healthy body has been abundantly evident in the lives of many practitioners of my acquaintance and has contributed very largely to their success: in none, perhaps, more so than in those who, by virtue of good work well done, have come to the front and are taking leading positions in their profession. It is not only the manner or quality of work which tells. The very ability to do more than others for years together, which comes from extra physical strength and endurance, has given some men an opportunity of forming an experience beyond their age, and enabled them to reach a point in advance of their fellows which they could never have gained without a splendid physique as the basis of their labour. And what shall I say regarding the want of this? It hampers a man at every turn, and though it is by no means fatal—much of the very best work of this and every age having been done in spite of physical weakness—yet animal strength and spirit, and the natural courage and unconscious power which go with it, are of the very essence of success.

Some of the very saddest recollections of my life are of eight professional friends—fellow-students—nearly all of about my own age, but not all students of this hospital—in each of whom this power was gratuitously and irretrievably lost by the incurrence of syphilis in early life. One who was well known in the athletic field and was the champion high jumper of his day succumbed to paraplegia. Another, a brilliant student, who took his Fellowship with me and shortly afterwards obtained a good hospital appointment, gradually lost his reason and died of brain lesion. Another, somewhat similarly affected, recovered slowly from specific hemiplegia, but with more or less impaired function and brain power. Another became blind. Another suffered and, I believe, died from the effects of stricture of the rectum; and yet another, who probably possesses, or did possess, exceptional teaching ability which might have been put to noble use, became affected with locomotor ataxy, and now lives a brave but comparatively inefficient life with crippled power and feeble health. I could go on if I wished and could, if it were justifiable, give names and dates and circumstances, but I have probably said enough. Again, I could, of course, append

to this list a companion one of lives which have been more or less ruined by alcoholism, but sad as are some of the cases it would include, none strike me as quite so tragic, so irremediably hopeless, as those which I have narrated. The steps leading down to such tragedies are unclean and dangerous. There is no necessity to tread them, and you must bear with me if I venture again to insist on de Tocqueville's definition of life as not only something entrusted to our charge, but a trust which must be carried through to an honourable end. Dishonourable—or rather, perhaps, unhonoured—ends lie in wait for all of us who are careless of the sacred nature of the trust, and though suffering may hereafter find its outcome in redemption this is neither “here” nor “now.”

In dealing with mental gifts and acquirements I find a difficulty. The field is a restricted one. The portals of the profession are guarded, and wisely guarded, by entrance examination, and all throughout the course your progress is tested by repeated examination, so that no one of really feeble or deficient intellect is likely to gain admission. A clear brain and good reasoning powers are undoubtedly needed for the proper understanding of most of the higher problems of medicine and for the prosecution of all original work, but the bulk of the studies in which you will be engaged require rather application than brain power. As anatomists you must know the human body as the good cabman knows his London; in microscopical anatomy and physiology you learn to know the buildings of which the city is made, their several uses and the work that goes on in them; while in bacteriology you learn to recognise—and by several alluring devices to hunt, confine, and tame—the various animals, domestic or wild, which may seriously infest the city.

In all your studies, even the most advanced, of practical medicine and surgery the simpler mental processes of observation and memory are those which will engage you most, and though to be a really good observer demands a quick perception, undivided attention, and constant practice, no one who has done fairly well at school need be seriously afraid of the mental strain involved by the study and work before him. On the other hand, there is plenty of simple steady work to be done day after day, and there may be some danger that the man with quick and able mind may under-estimate the importance of the daily “grind.” We all of us know the brilliant student, the pride of his school and his college, who occasionally, from first to last, carries all before him and that easily; but on looking back I am rather astonished at the number of good men I can recall to mind, clever men, men whose mental endowment was, if not of the first rank, yet far above the average, who still, for some reason or other, failed to fulfil the promise of their youth. On the other hand, I can remember some men who were naturally not clever or brilliant, whose brains, in comparison with their fellows, were slow and dull, who, in spite of this, by taking rather longer time to do the requisite work, did well, some one or two achieving high distinction. For no man knows a thing so well as he who has had hard work to learn it, and no one, when the lesson is learnt, can so well understand the difficulties of those below him and therefore so perfectly help them. It would, of course, be utterly wrong to argue from this that quickness of perception and intellectual ability are of little worth. They are in one sense the special desiderata of the age. So full is this of rapid change and progress that a certain sharpness and alertness of mind are absolutely necessary in order to keep abreast of the times and occasionally to obtain a chance of leading in the van. In no branch have we seen this more than in surgery, but it applies to almost every calling now, and he who lingers long upon the way is left behind in the race. You know this, you hear it spoken of, you read about it in the daily papers, and the necessity for keenness of intellect, for taking advantage of every kind of technical training, for promptness, hustle, and despatch, is preached—and rightly preached—at every corner.

If this were an age in which these things were undervalued none could speak more strongly than myself on the incalculable advantage of a good brain, trained by education to the very highest pitch of excellence, and therefore enshrining an intelligence well tempered and acute. But, of itself, this does not necessarily command the highest and most permanent success. Even in the life of scholarship or science, where the value of the intellect rises immeasurably, there is still something in the man outside it on which its beneficent use depends, while in the actual practice of

professional life thought must be united to action at every turn and both be controlled by healthy judgment for fruitful service. Indeed, the most marvellously gifted man I have ever known, whose powers of intellect and of expression were quite phenomenal, who was, in thought and practice, almost a generation ahead of his contemporaries, must be held to have failed of his proper destiny for want of something—some directing and controlling force—which might have kept the fountain of his genius purer, free from the extravagance of personal ambition and from the mud of unwise and often unjust controversy. And, as I think of these things, I recall also the names of three other of my contemporaries whose histories may possibly be familiar to you—three great Englishmen, men of commanding ability and promise, the sun of whose reputation and career set when it was yet morning, and in one case, that of perhaps the most brilliant and fascinating intellect my age has known, with a “horror of great darkness.”

What, then, is of greatest value? If life has taught me anything it is that a high moral purpose is the most important factor in one's life-work; in other words, it is character rather than intellect which determines true success. Now I do not think that one believes this or realises it in what is called “student-life.” We and our fellows are “gentlemen.” The main moral virtues—truth, honour, courage, temperance, gentleness—we take for granted. The real differences between us, the differences that “matter,” appear to be those of body and mind, and if we are deficient these are the ones that trouble us. Broadly speaking, this is a healthy view to take. It usually argues that the foundation-principles of morality are so well laid that, though possessed in varying degree, no one is without them, and the atmosphere of *noblesse oblige* engendered by this faith helps many a weak man to act up to the standard of those around him. But, little by little, there comes disenchantment. The friends whom we have trusted fail us; some men we meet take advantage of our youth and inexperience; some astonishing lapse of high principle in the conduct of one or more of our fellows startles us; or, on the other hand, some good thing well done by another—it may be some brave act or the ready owning of a fault—arouses our own inner consciousness and calls forth the involuntary question, “Should I, could I have done the same?” The life of the great city in which we find ourselves begins to alarm us by its injustice and oppression. Its hideous contrasts, the slavery of the poor to the rich—quite as real as that which existed in pagan Greece and Rome, but no longer open and naked and unashamed; the separation and isolation of the successful from the unsuccessful; the hypocrisy of society, in which vice is frowned upon openly but encouraged in secret, in which the highest and holiest things are prostituted to ignoble uses; the hopelessness of obtaining any collective effort to alter this,—all strike upon the dawning consciousness with confused but painful clamour. In one way or another we wake from dreams and “make-believes,” finding that real life is different from what we fancied. We strive, perhaps, to do right and have to walk in hard places, while others, with lax principles, achieve a kind of success—a success, however, that is worse than another man's failure, a success which cannot be touched with dissecting forceps. As life opens out before us, with cares and temptations and sudden tests for which we are unprepared, most of us, if we are honest with ourselves—I speak from my own experience—find that we, too, are somewhat deficient: that industry, or perseverance, or courage, or sincerity, or self-control—or other virtues I have not named—are not so perfect in us as they should be, and there is no school of morality other than the questionable and polluted one of life itself around us in which we can study and train and become stronger. And then we finally realise—rather late, perhaps—that these, after all, are the things that matter most.

It would be impossible for me now to consider all the good qualities which go to form the perfect or ideal physician or surgeon, but if you ask me what are the most important of these, without which—or the determination to possess them—it is hardly worth while entering on the actual practice of your profession, I should put in the first place love of truth, then love of one's kind, and then love of service. By love of truth I mean not only the love of careful and exact statement, though this is of the utmost value, but also the discoverer's love of fact, for the gaining of which he will endure hardship. By love of one's kind I mean a ready interest and sympathy in men of all classes, a

genuine recognition of brotherhood which will make you enter into their difficulties and sorrows as your own, respect their helplessness, and have patience with their ignorance. By love of service I mean that disposition or attitude of mind and body which finds its chief delight in helping others. If a man possesses these qualifications, or strives for their possession, though he may have taken no honours at his university people will trust him, because they can believe in his word and his purpose; they will understand him, because he is not ashamed of kinship; they will love him in proportion to his work for them. And the work of such a man will be good work. It may have the limitations inseparable from the measure of his attainment, but it will be free from humbug or pretence, and every essential accessory within his own control (such as the strictest surgical cleanliness and care) will conspicuously mark his conduct of the cases entrusted to his charge.

But what if we know that we are wanting? What if some of you feel (as I have felt) that neither the body, nor the mind, nor the character that we desire is ours to-day? What if some of us know that we inherit weaknesses as legacies from those before us? Then, whatever may be said regarding bodily attainment (and this is far more capable of development under culture and training than many have imagined), of this you may be certain, that growth of mind and character are practically illimitable, and that there is probably nothing short of insanity that cannot be overcome by education in the highest sense of it. In these days, when a little truth is occasionally written in scattered papers on the subject of heredity and almost any amount of fictitious nonsense dealing with this question is scattered broadcast, it seems necessary to preach again the gospel of true education. Believe me, there is no weakness you cannot grow out of if you set your heart upon it, there is no strength or goodness that you may not aspire to and in some measure attain.

*"Μακάριοι οἱ πεινῶντες καὶ διψῶντες τὴν δικαιοσύνην, ὅτι αὐτοὶ χορτασθήσονται."*

But the way is long, and the heart must be set upon the goal.

"The road winds up-hill all the way,  
Yes, to the very end,"

and the hardest lessons are not to be learnt at the beginning. This is why I said that a high moral purpose was needed rather than a catalogue of virtues. It is the taking of the up-hill path that is the important matter; the doing of our duty to the best of our ability day by day that brings with it light and leading. For as the distance lengthens the prospect widens; we get out of the narrow defiles and tangled mazes of the earlier journey, and though the ascent becomes steeper and more painful, more and more of its direction becomes open to our view. Of course, there are times of darkness when we can no longer, perhaps, see the way, but if we look upwards there are always the stars to guide us. Even when these are hidden, if we wait patiently, quietly, perseveringly, the cloud will finally "lift," for the stars are always there. Before the ending, too, the sights and scents and stillness of the everlasting hills are about us and inspire calm and quiet confidence.

But will not the trend of thought I have been pursuing—the influence of character on individual life—admit of a wider application—the influence of character on national life? I have lately been visiting some towns in the South of France, where remains of Roman occupation, of Roman architecture, and of Roman life are both plentiful and striking. At Arles, which is a veritable museum of antiquities, the arena is still standing: colossal, magnificent, built on a scale rarely or never attempted by us for any permanent building. It holds easily 25,000 people, and is still occasionally used on great public festivals. Close by are the ruins of the Roman theatre, and still further on we find the old burial-ground, or Elysian Fields, the cemetery of "les Aliscamps." Here we may note the care and love and reverence which the Romans lavished on their dead: the massive tombs, many of them double for husband and wife; the touching inscriptions commemorating the life and work of those who had gone before: here, a builder of ships; there, a young girl, fond of, and proficient in, the art of music, her tomb carved with representations of the mandolin or guitar, the early organ, and other instruments of music; or here, again, the tomb of a boy of 17 whose sorrowing friends mourn his premature decease. Again, if we pass to the Musée Lapidaire and see the carving, the jewellery, and the pottery of these days,

some difficult to imitate and impossible to surpass; if we look at the faces of these Romans preserved to us in marble, strong, fine, intellectual, like the best English faces of to-day (and there is much more Roman blood in English people than many have supposed); if we look at the sculptured heads of their children, and particularly I might single out the head of the boy (supposed by some to be a son of Constantine) which for purity and beauty is perhaps the most wonderful fragment of realistic sculpture in the world,—if we consider all this, it seems impossible to conceive how these men, so great, so powerful, so wise, so loving, the successful colonisers and rulers of nearly all of the then known world, could have lost their empire and become merely a shadow and a name. If history is to be believed—and we can read it directly in the later literature of their race—it was not intellectual gifts which became wanting, it was not directly bodily strength that failed, but it was the national character which slowly became depraved. Sapped by the loss of national faith, the increasing growth of luxury and softness, the limitation of families, the relaxation of marriage ties, the elevation of the wanton and courtesan, the disgust of service, the importation of foreign slaves and soldiers, who, many of them, became better and greater than their masters—it was the gradual corruption, effeminacy, and moral decadence of the race which led to its downfall and its ruin.

And what of the national character of England in our own days? Are there not some indications of similar dangers? If you think so—and I could give you many reasons for this fear did time permit—individual awakening may do much to help yourselves and the profession which you have chosen. It may finally arouse collective action and do much to help England. Gentlemen, we have been passing, and are still passing, through a time of "sifting," as every time of war must be. Older and, as I think, purer ideals are again coming to the front. We begin to realise that the "battle is to the strong," and that the real wealth of a nation consists not so much in her material prosperity as in the number of healthy, upright, and manly lives who can give themselves to her service and protect her in the hour of need. Such have not been wanting in our recent struggles, men who

"Never turned their backs but marched breast forward,  
Never doubted clouds would break,  
Never dreamed, though right were worsted, wrong would triumph.  
Held, we fall to rise, are baffled to fight better,  
Sleep to wake."

But we want more of these, and of this faith or spirit which ensures the final victory. You who will be the medical attendants and advisers of the future generation may do much by steadily honouring and upholding higher ideals of individual, family, and national life to infuse a new and healthier spirit into the coming age. For it is in the spirit of Browning's epilogue that the hardest tasks are always accomplished—it is in this spirit that a nation may sometimes be born again.

## Abstracts OF

### INTRODUCTORY ADDRESSES, ETC.,

DELIVERED AT THE

MEDICAL SCHOOLS

AT THE

Opening of the Session 1901-1902.

UNIVERSITY COLLEGE HOSPITAL.

INTRODUCTORY ADDRESS BY RISIEN RUSSELL, M.D. EDIN.,  
F.R.C.P. LOND., ASSISTANT PHYSICIAN TO THE  
HOSPITAL.

DR. RISIEN RUSSELL, after welcoming the old and new students, expressed the hope that none of the latter were entering on their medical studies with the set determination that they were going to be specialists, as such a course was fraught with great danger. Their object should be first to become good all-round men, well versed in every branch of their profession, as no one could become a good specialist who had not fortified himself by a thorough general knowledge of medicine and surgery. After insisting on the

importance of anatomy and physiology he pointed out how essential a knowledge of bacteriology had become to the medical man and how chemistry, always a most important subject in the medical curriculum, had acquired additional importance since a knowledge of chemical methods had become so necessary to the bacteriologist. Chemistry had also become more important because chemical analyses of the blood, the excreta, and the contents of the stomach were now indispensable in the diagnosis, prognosis, and rational treatment of many diseases. Special attention ought to be paid to chemical pathology and they might consider themselves fortunate that there was now a clinical laboratory in the new hospital that Sir Blundell Maple's splendid liberality had provided for them, where they would be able to learn how to investigate some of the complex problems of disease by methods that were calculated to make diagnosis less conjectural and treatment less empirical in the future than they had been in the past. In congratulating the students on the profession they had chosen he said that it would give them every opportunity of increasing their intellectual powers and of widening their sphere of knowledge even far beyond the limits of the subjects with which they would be directly concerned. It would afford them due scope for the full exercise of all their faculties, and if they made good use of their time they would in the end have the inestimable satisfaction of knowing not only that they had done good work, but that it had been for the benefit of their fellow-beings.

He next called their attention to the special advantages which there were in entering the medical profession at the present time. No other profession could hold out the prospect of so quick a return on the outlay that students were obliged to make. In support of this view he pointed to the fact that during the last seven years there had been a falling-off in the number of men entering the medical profession, so that there were now 1660 fewer men qualified to practise medicine than there would have been had the same number joined the profession each year since as did so in 1893. In the meantime, as the figures of the last census showed, the population of the country had increased to the extent of over 3,500,000 during the last decade. The colonies had always supplied many good openings for men who had received their medical education in this country and they might be expected to continue to do so, but to South Africa more especially he felt justified in looking for a large number of openings for young medical men when the development of the country was proceeding with after the termination of the war. Then, again, the vigorous and laudable action of the General Medical Council in suppressing unqualified assistants and in stamping out the iniquitous system of "covering" had made many openings for qualified men. The expert committee appointed under Mr. Brodrick's presidency had been an earnest of the determination of the Government to reform the Army Medical Service, and the committee's report that had just been published contained provisions that could not fail to increase the popularity of this service. There was ample evidence to show that the Admiralty would have to follow the example of the War Office and institute reforms in that branch of the service. So unpopular had the medical service of the navy become that but few candidates could be induced to come forward to fill the vacancies that were being caused by resignations and retirements. A good example of the state of things that obtained was to be found in the fact that 14 vacancies were advertised in August and only seven qualified medical men responded to the call. Of these only four were available, as one was found to be physically unfit and two failed professionally to satisfy the examiners. Reforms in the medical services of the army and navy would not only provide good openings for young medical men, but as more men were attracted by the services those available for the civil population would be reduced and the chances that a young man would have of making his way in private practice would thereby be greatly improved. How small was the reserve of young medical men, even at the present time, had been demonstrated by the experiences connected with the South African war, for those surgeons required for the army had not been supplied without inconvenience in other quarters. Provincial and other hospitals had had difficulty in securing men to fill posts as house physicians and house surgeons; steamship companies had experienced a similar difficulty in getting medical officers; and many medical men in general practice had not found it easy to take a holiday this year

either because it had not been possible to find locum-tenents or because the remuneration such substitutes now received was more than many practitioners could afford to give. These various considerations led him to conclude that the medical man who was ready to practise his profession in five or six years' time would be in a most satisfactory position, so that students now commencing their medical studies could look forward to finding openings for the practice of their profession five years hence with a degree of certainty that did not obtain in any other profession.

He complained of the unsatisfactory public status of the medical profession. From the members of no other profession was so great an expenditure of time and labour required, for a man had to devote five years of his life to study before he could become qualified to practise. The time was not too long, as it was to the best interests of the community that a liberal amount of time should be devoted to acquiring knowledge that was so essential to the well-being of mankind, but a profession whose services to the community were admittedly so important as to need such careful preparation was one that was justified in looking to the State for some better signs of appreciation of its worth than had hitherto been forthcoming. The composition of the House of Lords supplied an example of the small value placed on the medical man, for while that assembly included clergymen, military men, and lawyers, only one medical man had as yet been deemed worthy of a seat there. He submitted that medical men were as much needed in the deliberations of an assembly where matters of the greatest possible moment to general medicine and to sanitation were decided, as bishops, generals, and lawyers, and that there were to be found in the medical profession men as distinguished and as high in the social scale as the members of these other professions. He further contended that the services that the medical profession had rendered to the community called for such recognition of its most distinguished members as would raise the public status of the profession to a higher level. While feeling that they had a right to look to the State for better appreciation of their worth, he could not but admit that the unsatisfactory public status of the medical profession was in some measure due to the way in which some of its members deported themselves, even when they occupied high professional positions. Men of the stamp to which he referred created an unfavourable impression on the public mind which was not readily effaced, so that in forming an estimate of the profession from a social standpoint the public remembered them and forgot the many polished gentlemen that there were in its ranks. He accordingly exhorted the students so to order their lives as not only to sustain but to raise the general tone of the profession. Another reason why the profession did not rise to its proper level in public estimation was the difficulty that the public appeared to have in distinguishing between the medical man of the present day and the apothecary of the past. They appeared to consider that the two were much the same, and this erroneous idea was fostered by the circumstance that so many medical men still dispensed their own medicines. He recognised the difficulties that would have to be contended with in many an out-of-the-way part of the country were medical men not to dispense their own medicines, but such cases were in the minority, and the majority of medical men in private practice could discontinue dispensing medicines with the greatest possible benefit to themselves and to the public. The time now spent in doing druggists' work could be utilised to far greater advantage to themselves and to their patients if it were devoted to reading to keep themselves informed of the advances that were constantly being made in every branch of medical science; abolition of the practice would help to educate the public to regard the medical man as something superior to a mere vendor of drugs and would teach them to value him for his advice instead of for his medicine. The inability to appreciate the difference between the medical man of the present day and the apothecary of the past probably accounted, in part at any rate, for the frequency with which people consulted druggists, and so far did they fail to understand the difference between a qualified medical man and a druggist that it had been recently reported that a coroner and his jury actually accepted the evidence of a druggist as to the cause of death of a clergyman whom he had been attending.

He next spoke of the school to which the students had come to receive their medical education and said that he could do so more freely than would have been possible for

many of his colleagues, as in eulogising University College they would have been lauding themselves, in that their brilliant achievements and the achievements of some of their predecessors had done much to place the college in the proud position it now occupied among the medical schools of the metropolis. The congratulations which he received from his friends when he was fortunate enough to gain the appointment which gave him the privilege of addressing them were most of them couched in terms that either stated or implied that there was something that called for special congratulation over and above that which his appointment on the staff of any other medical school would have necessitated. Their comments confirmed what he had already known—viz., that the position University College occupied as a scientific school was very high, that its staff was composed of men of great distinction, that they had always enjoyed a great reputation for their powers as teachers, and that the standard of teaching had always been high. The influence that University College had had on medical teaching in London was very great. There was not a medical school in the metropolis that had not numbered among its teachers men who had received their education at the college, and an even more wide-spread influence had been exerted on the medical teaching in this country, in that at various centres out of London where men assembled to receive a medical education the names of University College men were prominent among those whose duty it was to conduct the teaching. The Universities of Oxford and Cambridge were numbered in the list and, as most of his audience knew, one of the Scotch universities had comparatively recently secured in a former student and professor of the college a man whose name ranked among the first physiologists of our time. The scientific education received at the college was unsurpassed by anything that could be obtained elsewhere in this country, and the spirit of scientific research that was active had led to brilliant achievements by those who had worked there and by others who had gone forth to prosecute their researches elsewhere.

He begged his hearers to cultivate the spirit of scientific inquiry. Every scientific research, if properly conducted, might be expected to disclose some new fact, and this was the only way in which true progress could be made. The medical man was in a peculiarly enviable position in that most of his researches when crowned with success tended in a more or less direct way to promote the welfare of mankind, some of them indeed being directly concerned with the relief and others with the prevention of human suffering. Dr. Ferguson's presidential address at the last annual meeting of the British Medical Association was too fresh in his memory, however, to make him unmindful of the fact that inestimable benefits had been conferred on mankind by the discoveries of men who did not belong to the medical profession. It was to men of science that they owed every real fresh advance in medicine. The so-called practical man could do little more than apply and utilise the discoveries of the scientist. In exhorting them to cultivate the spirit of research he did not in the least wish them to neglect the part of their training that would fit them to become practical physicians and surgeons. A belief prevalent among some people that a man could not be both scientific and practical, and that the cultivation of the one faculty must of necessity be at the expense of the other, he regarded as a great fallacy. Medicine and surgery could only be expected to be advanced by a proper commingling of the scientific and the practical, so that scientific principles might find practical application in the elucidation and treatment of disease. If they required any stronger incentive to induce them to aim at being able some day to advance the science of medicine by their own investigations, let them read of the horrors of surgery in the days before antiseptics were introduced in the treatment of wounds, and compare that picture with what they saw when the time came for them to take up their duties as dressers in the wards of the hospital connected with the college. He would be surprised if the contrast between the two pictures did not stimulate them to emulate the example of men like Pasteur and Lister, even though they felt mere pigmies compared with those giants. Well might Lord Lister ignore the vituperations of a gang of agitators who, in the face of such an incalculable benefit as he had conferred on his fellow-beings, dared to treat him to some of the abuse that they visited on all those who by their researches sought to mitigate the sum total of human suffering. He expressed the hope that he was addressing some who had completed their medical

studies and who now wished to take up research work, at any rate for a time. The inducements for men to devote their time to scientific work were few, as the scientific spirit was not yet sufficiently alive in this country. Neither the Ministers who controlled the purse-strings of the country nor private individuals who possessed fortunes that they were anxious to utilise for the public good had had the scientific education necessary to make them realise that the true way to promote the welfare of the nation was by endowing research. More research scholarships were needed, and more laboratories where the atmosphere was saturated with the spirit of research and where the directors received emoluments that were sufficient to allow them to give their whole time to the prosecution of their own researches and to the directing of the investigations of others who worked under their supervision. He was not altogether without hope of aid from the State, for although statesmen had not shown that they in the least understood what an incalculable amount of good might be expected from encouraging men to devote their lives to research, the keen interest that His Majesty the King had always taken in scientific matters and his gracious recognition of the value of research, at no time more clearly expressed than in connexion with the recent Congress on Tuberculosis, would, he trusted, lead Ministers to recognise the importance of this question. Meanwhile, he looked with confidence for help through the munificence of private individuals. He had great hopes that the feelings which prompted Lord Iveagh to found the Jenner Institute of Preventive Medicine and which induced Mr. Andrew Carnegie to give £2,000,000 to the universities of Scotland were not wholly wanting in other wealthy men in this country, and that the wonderful foresight and magnificent liberality of these two men would serve to stimulate others to emulate their excellent example.

#### MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY THOMAS H. KELLOCK, M.A.,  
M.D. CANTAB., F.R.C.S. ENG., ASSISTANT SURGEON  
TO THE HOSPITAL.

IN welcoming the new students the opinion was expressed that rarely of recent years had the prospect in the medical profession been brighter than at the present time. Various causes—amongst them the addition of a year to the length of the curriculum, the substitution of qualified for unqualified assistants, the war in South Africa, the widening fields in the colonies, and the prospect of better conditions in the army—had all, it was stated, had their share in considerably increasing the value of the services of a well-qualified man. The advantages to the average man of an education at one of the smaller schools were mentioned, chief amongst them being the comparative ease of obtaining the resident appointments and the great value and recommendation of these in later life.

The main part of the address was devoted to a consideration of the relations between students and the hospitals during the time of their pupillage and afterwards. Passing over briefly the time a student passed in the school before commencing practical work in the wards and out-patient rooms, and pointing out the importance of a student making the best use of that time and learning well work that he was little likely to have to go back to, and of his getting into a good habit of work, it was said that in the future it was possible that the time when a student began his practical work might mean for all what it now meant for those who came from the universities a first introduction to the hospital. It was easy to forget what past and present students owed to the hospitals, the enormous sums of money which had been contributed to them had enabled them by years of useful work to build up such a reputation that they had become the resort of the poor directly accident or disease came upon them. They could thus place at the disposal of the student a large mass of clinical material under the best conditions for studying it, one of these being the fact that in a hospital a patient consented to, and expected, a proper examination. The hospitals, too, provided the funds for acquiring the new and expensive apparatus that the progressive medicine and surgery of to-day rendered necessary, and students as well as surgeons got the advantage of this. It was then considered what a student could do for the hospital in return. By carefully performing his duties when acting as clerk or dresser he could not only help himself in acquiring knowledge but also help in the work of the hospital. It was an

important duty of students at all times to be careful of their behaviour and conversation to and in front of the patient. In the wards and in the out-patient and casualty departments hospital patients and their friends were not only observant but had a propensity for discussion amongst themselves; and the welfare of an institution gained or suffered very much by the behaviour, not only of those who had actually to deal with the patients, but of all those who were present, even if they were only onlookers. To learn how to deal with patients was a not unimportant part of a medical education, and very often a man's success, or the reverse, when he went into practice depended as much on this as on his professional knowledge. At the start the young practitioners generally had to deal with patients of a class differing little if at all from those he had seen at the hospital, and it was most important, too, that he should have at least some experience in the management of children and of the parents who bring them. All of these things he could learn at the hospital, and in learning to do them properly he could be of use to the institution. The duty of students to their hospital when outside its walls was obvious. Generations of self-respecting and hard-working men had long since dispelled the idea that medical students were necessarily ill-behaved or rowdy, and those of to-day knew very well that by their behaviour and conversation they could bring credit, or the reverse, on an institution to which they owed so much.

When a man had become qualified and left the hospital to start on the real work of his life there might still be a bond of union between him and his hospital closer than that which connected him to his school or university. He had probably done with the latter altogether, but at the hospital there was always work going on that was of use and interest to a medical man, and if he wanted to spend a few days or weeks in brushing up his knowledge there was one place above all others to which he should go, and that was his old hospital. Students in all departments of the hospital should always make welcome those who had preceded them and who had an equal right with themselves to what was to be learned there. A fact that was not without its lesson was that qualified men were often more interested than the student in the treatment of patients, knowing by experience how important this and also the rapidity with which they could get their patients well were in practice. A correct diagnosis was the real scientific foundation, but would not in itself cure the patient, although it was everything in directing the medical man to what was the correct treatment. There must, the speaker said, be something very wrong with a hospital, its staff, or the medical man himself if he could not find enough, and more than enough, there to satisfy him when he paid it a visit and to prevent his having recourse to post-graduate courses and such like, at any rate for ordinary medicine and surgery.

A very important feature in the relations between medical men and the hospitals was the practice of their patients resorting there for advice and treatment. Statistics showed what a large portion of the population went to the hospitals at some time or another and the question as to how many of them were depriving medical men of their fees by so doing was a difficult one to decide. The majority of the out-patients, for example, appeared to be fairly well-to-do, decently dressed, and sufficiently fed. The very poor and partially starved were decidedly in the minority. Was this because the population on the whole was well-to-do or was it also because the very poor could not afford to live and be out-patients, but had to go to the infirmaries if they could not be admitted to the hospitals? The opinion was expressed that the patients as a rule made no pretence to be worse off than they really were and instances of their dressing in shabby clothes to obtain admission were very rare. The causes that brought such people to the hospital were considered. It could hardly be that they saved money by going, for often their travelling expenses, to say nothing of their time, must be more than a visit to a medical man would cost them. One of these causes was the great confidence that the public had in the hospitals and in the potency of the medicines given them there; they thought that their ailment was sure to be recognised and the right medicine given them. Many medical men had not acquired the art of gaining their patients' full confidence and they came to the hospitals only to see if there was anything more than they had been told the matter with them. Often, too, patients would submit at a hospital to a more thorough examination than they had allowed their medical

man; in this respect at a hospital they had an advantage and were sometimes able to discover the cause of an illness the symptoms of which had for a considerable time resisted treatment. The ways in which medical men and the hospitals could be of mutual assistance were considered, and if at times the relations between them were strained on account of the abuse of the latter by patients, it should be remembered that there were three factors concerned—the hospital, the medical man, and the patient: and often the tendency of each of them was to blame the others rather than to try to remedy that part of the fault which was their own. It was the duty of the authorities at the hospitals to keep a very watchful eye on their wards and their out-patient and special departments and to prevent the admission to them of unsuitable patients. It was quite possible to decline to treat them in such a way as to leave undisturbed the relations between them and their medical man, especially as they very often applied to the hospitals under quite a misapprehension as to the objects of these institutions. By working together the hospitals and the general practitioners could, and probably did, educate their patients and the public generally in such a way as to keep this abuse of the hospitals within very fair limits.

#### LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY F. W. ANDREWES, M.D. OXON., F.R.C.P. LOND., PATHOLOGIST TO ST. BARTHOLOMEW'S HOSPITAL.

DR. ANDREWES said: My first and most pleasant duty is to bid a hearty welcome to the newcomers to this medical school, and I trust that you will gain here not only the adequate training in the profession you have chosen which this school is now more than ever fitted to give you, but also a number of firm friendships and pleasant memories which will remain for your whole lives.

I have next to say something to you—not new, indeed, but I hope true—about the methods of medical education, and especially about the value of a rational perspective in your studies. The enthusiasm for work, which I have found even keener amongst women students than amongst men, entails the risk that you may spend time over things that matter little, leaving insufficient space for more vital matters. It should be the main function of your teachers to direct your energies into the most important channels. No one can in five, or even in 50, years learn all that one could wish about disease and its prevention and treatment. You have to go on learning all your lives and a healthy sense of ignorance is a saving grace. But there are three things which you must learn in your five years of medical study. You have to learn how to learn. Then you have to learn as much as you can of those things which are of immediate and cardinal importance and which will serve as the groundwork for future learning after you commence practice. Lastly, you have to learn how to set forth what you have learned in such a manner as to persuade a board of examiners that you are fit and proper persons to be let loose on the public as qualified medical practitioners. From books and from lectures you may acquire by rote a mass of useful facts, but this is not living knowledge. What you learn from your own observation and experience you will carry with you with an intensity of conviction far exceeding that gained at second hand from reading or attending lectures. For nearly a thousand years during the middle ages medical knowledge stood still because people merely read Hippocrates and Galen and did not observe and experiment for themselves. Modern medicine and modern science date from the time when reverence for tradition was swept away. Nowadays all that we care about is whether a thing is true: we are ready to take the greatest pains to prove or disprove the truth of any given assertion, but we care not who makes it unless it can be shown to be true. Koch is the greatest living bacteriologist, but when the other day he came to London and asserted that human and bovine tuberculosis were not the same thing we did not bow down and accept the statement. We began to weigh the evidence, and all over the world experiments were started to see whether what Koch had said was true. The female disposition is perhaps more confiding than that of the male, so that you must especially be on your guard against accepting as final all that you see in print or hear from your lecturers. Your laboratory and hospital work will give you opportunity for checking and testing for yourselves a large part of what you are taught, and you will not

find that your teachers are annoyed with you for questioning their teaching. You must cultivate your powers of observation, and you will find that making drawings and writing descriptions from actual things or patients will be a valuable help to you.

What you have to learn is largely determined for you by the regulations of the General Medical Council and the examining boards, and the examinations you have to pass appear to shut off your studies into a series of water-tight compartments. You must not accept this point of view; every stage in your studies is a necessary preliminary to the rest. The pure sciences, physics, chemistry, and biology afford you valuable mental training, but they form, also, the absolute basis of physiology. Nevertheless, you have time only to acquire what is absolutely necessary; you must not wander into even the most fascinating by-paths of pure science. It is difficult, again, to exaggerate the importance of anatomy, but even here there are degrees of importance. The knowledge of anatomy required of the surgeon is something like the topographical knowledge of London required of a cab-driver. No cabman can know every by-way in London; there are innumerable alleys down which no cab can drive. But he knows the main arteries of traffic with absolute precision and trusts to his general knowledge of the lie of the land. And in anatomy you have to master the essential and cardinal facts with precision and gain further what general knowledge of the lie of the land you can acquire. Your teachers will emphasise for you the facts which are essential in medicine and surgery.

Physiology must lie at the root of your medical practice. One of the soundest physicians I ever knew, when asked which was the best text-book on medicine, used to reply, "Foster's Physiology." If your watch keeps erratic time you take it to a watchmaker who understands the exact function of every part of its mechanism and who can so adjust its different actions as to make it again a good time-keeper. So you must try to learn how the different parts of the complex human clock-works act together for that perfect balance which we call "health." Then you will be in a position to understand what may happen when the works go wrong. You have to learn physiology in order to understand pathology, and it will help you in surgery as well as in medicine.

Amongst your final studies pathology must take a foremost place. Diseases are departures from the normal in every sort of direction and to every possible degree; hardly any two cases are exactly alike, and if you have acquired a sound knowledge of pathology you will be in a position to look at each case on its individual merits. The methods by which pathology is studied are precisely those used in other pure sciences—observation and experiment; and it is this science which is placing medicine and surgery on a scientific basis. It is plain that a sound knowledge of disease is an indispensable preliminary to its reasonable treatment. In medicine and surgery and their various branches you will have to apply what you have learned to the treatment of living patients, and here the root of the matter is clinical diagnosis. The secret of successful diagnosis lies in painstaking and accurate observation and in reasonable deductions from the observed facts. Treatment is likely to be successful in proportion to the accuracy of the diagnosis. You will need a sound knowledge of pharmacology and you will have to acquire manual dexterity in your surgical work; nor must you overlook the details of nursing.

There are also certain mental and moral faculties which your medical education should cultivate: you will need the training in responsibility and confidence which is given by having to meet medical and surgical emergencies. You must be considerate and tender towards your patients, who come to a hospital primarily to be cured and not that you may learn from them. Never forget that you are women: the feminine character may have its weaknesses in some directions, but in others it has a strength and helpfulness for which the medical profession offers to women an abundant scope for usefulness.

In conclusion, let me say a word about your examinations. In order to pass them you must know your work, but in addition you must be able to show that you know it, and herein lies the art of passing examinations—an art which can be acquired with practice if you are naturally deficient in it. It is the art of exhibiting your wares in a taking style, so that the examiner can see at a glance what you really know. A neat and clearly-written paper may satisfy

him where, with the same amount of knowledge on your part, an ill-written and confused production may result in a plough. You must, therefore, cultivate the art of serving up your knowledge tastefully as an important subsidiary matter in your medical studies.

#### ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS BY G. WILLIAM HILL, M.D. LOND.,  
SURGEON FOR DISEASES OF THE EAR TO THE HOSPITAL.

DR. HILL commented on the fact that some 2000 men and women should every year enter on an extensive and expensive course for the purpose of entering a profession that was already moderately overstocked. It was doubtless a question with many whether these young persons were wise and whether it was really necessary to go to the trouble and expense of a medical education. The law hindered no one from practising on the credulity of the public. They lived in an age when there was not only a survival of superstition and a belief in the occult and in quackery of all descriptions, but in an age when there had been a positive revival of an hysterical form of occultism, a jumble of pseudo-science and irreligion. Faith-healing, of which so-called "Christian Science" was the type, was a money-making concern, and a diploma from a College of Psychic Healing could be obtained after a course of study not extending beyond three weeks, in some circumstances in three days. Medicine and religion in remote times grew up side by side and their exposition was in the hands of the same individual, the priest-doctor, and a belief in the occult was therefore a factor in each. Even Hippocrates, who was the first to attempt to put medicine on an improved basis, jumbled fact and fiction and fable in his "humoral" and humorous system of pathology. Every physician of old claimed to be a miracle-worker in a small way on the strength of cures effected through the influence of the mind on the body—that is, by suggestion and expectant attention in functional diseases. The reverence of the Greeks for their dead prevented anatomical investigation. The facts and symptoms of disease, though accurately observed by the Greek and Egyptian physicians, were made to fit in with a fantastic pathology such as that of Hippocrates, or with an absurd philosophy like that of Aristotle, and to each of these was added the tincture of occultism inseparable from priestcraft in all times. This morbid influence to some extent declined in the time of Galen, but it began to luxuriate again in the Dark Ages in association with alchemy, astrology, necromancy, and religious superstition. Faith-healing, touching for king's evil, mesmerism, homeopathy, and clairvoyance, kept occultism going from the time of the Stuarts to the end of the eighteenth century, and the nineteenth century had been remarkable for the revival of the belief in spiritualism, mental telepathy, and "divine healing." Quackery, as represented by fraudulent institutes for the deaf, the sale of ear-drums, and panaceas for every ailment under heaven, appeared to prosper as of yore, and it would continue to do so whilst the majority of mankind were unthinking in medical matters and unable to throw off the occultism of the nursery. The supporters of quackery, Christian Science, occultism, and all forms of medical heterodoxy were found as often in the castle as in the cottage. Religion and theology have nothing whatever to do with the investigation and treatment of disease, nor is prayer recognised as a therapeutic agent in the treatment of organic lesions by orthodox practitioners.

#### PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

INAUGURAL ADDRESS BY ARTHUR P. LUFF, M.D., B.Sc.,  
F.R.C.P. LOND., PHYSICIAN AND LECTURER ON  
FORENSIC MEDICINE AT ST. MARY'S  
HOSPITAL.

DR. LUFF said: It is 27 years since it was my good fortune to be a student in this school, and I know of no greater honour and no greater pleasure that can be conferred by one's alma mater than for one of its alumni to be entrusted with the duty of delivering its annual address. The occasion is, moreover, a pleasant and an auspicious one, since this year marks the sixtieth anniversary—the diamond jubilee—of the Pharmaceutical Society. I do not propose this afternoon to attempt any historical survey of the progress of the society during these 60 years or to detail the immense amount of work performed by it and the consequent benefits accruing to pharmacy and to the public during that period.

The history of the society, together with a record of its work, was most ably dealt with 10 years ago in the inaugural address then given by that Nestor of the presidents of this society, Michael Carteighe. During the 10 years that have elapsed since the date of that address much good work has been done and many improvements have been effected in the school. In my opinion the most important reform effected during that period has been the abandonment of the first or preliminary examination and the requisition from everyone who desires to enter pharmacy of evidence of an education similar to that which every medical student has to produce. It is impossible to over-estimate the far-reaching beneficial results to which this important step must lead. It will raise the level of pharmacy more than any other reform that has ever been effected by this society. I also offer my congratulations on two events which have occurred during the past decade. The first is the invitation which the Pharmaceutical Society received from the General Medical Council to coöperate in the revision of the British Pharmacopœia—a responsible task which it is peculiarly qualified to perform and for the carrying out of which the research laboratory of this institution has been very appropriately utilised. The second very satisfactory event which deserves special mention is the recognition of this school by the reconstituted University of London, the professors of the school being now extra-mural teachers of the University. The founding of the Northway Butt Scholarship for research work in pharmacy, as distinct from chemistry, is another important event for which the society is indebted to the liberality and foresight of Mr. Butt. I regret that I am not able to place on record the adoption of a compulsory curriculum of study for the minor examination; such a curriculum is, in my opinion, sorely needed, and I believe it would go far to reduce the very high percentage of rejections in that examination.

Pharmacy is a many-sided calling and therein undoubtedly lies one of its chief attractions. The scientific part of the work of an educated pharmacist does not consist solely in the dispensing of prescriptions, important as that branch of his calling undoubtedly is. We hold him to be the responsible person for the preparation of drugs in suitable forms, and for the standardisation of those preparations, while the public have to look to him not only as providing means for the restoration of their health but also have to rely upon him for the safety of their lives. It is but a pessimistic and ignorant view to take that no great amount of skill or of scientific training is required to put together the ingredients of a prescription. Such a view does not recognise, and perhaps the public do not adequately appreciate, the great safeguard to them that the educated pharmacist is. It is no very uncommon matter for the medical man, when hurriedly writing a prescription, to make such a mistake in the dose of an important ingredient that disastrous results to the patient would follow the taking of the medicine if so dispensed; but now, happily, through the far-sighted wisdom, primarily of this society and subsequently of the legislature, the public safety is efficiently provided for. The pharmacist detects the error in the prescription and communicates with the medical man. The public are unaware of the means by which their health, and possibly their lives, have been protected, but how many of my professional brethren have gratefully and thankfully to acknowledge the tact, courtesy, and delicacy with which their attention is drawn to their mistakes by their pharmaceutical *confrères*? Again, it is no very uncommon matter for a prescription to contain such incompatible ingredients that perhaps the active, and, maybe, poisonous, principle of the medicine is wholly precipitated, and so might possibly be entirely taken in the last dose, with results which would probably be disastrous to the patient; but here, again, the skilled pharmacist acts as a guardian of the public safety by detecting and pointing out the error that has been committed. But, unfortunately, both medical men and the public are tending heavily to handicap the pharmacist in that important function, and are in great part rendering him impotent to safeguard the public health, for there is a growing practice which is rapidly threatening to undermine to a great extent what I consider to be the skilled and rational employment of therapeutic agents in the treatment of disease. I refer to the too general use of powerful drugs in compressed forms and of proprietary preparations. I do not for one moment wish to suggest that the various forms of compressed drugs have not their proper uses; undoubtedly lamellæ and tabellæ of active principles in the hands of medical

men are most convenient and useful for hypodermic and occasionally for other forms of administration; but it is the ready facility with which powerful drugs prepared in this form are obtained by the public which constitutes so grave a danger, a facility which is responsible to a great extent for the increasing practice of self-drugging—a state of affairs which I am afraid has been brought about by these preparations being so indiscriminately and so largely prescribed by medical men. To take one instance, it is to the ease with which such preparations can be purchased by the public that, in my opinion, is due in great measure the prevalence of the comparatively modern and excessively pernicious evil—the cocaine habit. Equally bad is the use of some of the proprietary preparations which are so speciously puffed; with the samples and laudatory advertisements of which the members of my profession are so profusely deluged, tempting them, as they do, to the slovenly and enervating habit of thinking that the writing of an order for such a preparation is the writing of a prescription and gradually rendering them absolutely impotent to exercise the true art of prescribing. Many of the preparations of that kind are, I believe, productive of infinitely more harm than the quack medicines which to some extent they are replacing, for the former are frequently powerful, and in unskilled hands dangerous, drugs, whilst the latter, though generally worthless, are to a great extent innocuous.

The fact is, that the art of prescribing—that is, of ordering suitable remedies in suitable forms for the treatment of morbid conditions—is declining; it shows a fatal tendency to be usurped by the manufacturer. I am bound to confess that the primary cause of this evil is due, not to any imperfections in the training of pharmacists scientifically to compound and dispense medicines, but to the altogether inadequate attention which is given to the teaching of prescribing at so many of our large hospitals and medical schools. I merely refer to this phase of the subject here, as I intend shortly to deal with it in another place and before those who are more closely interested in the preservation of this important branch of a medical man's duties. What a travesty on the art of prescribing it is for a patient to bring to a pharmacist a so-called prescription which merely orders say, No. 4 Mixture (Smith and Jones). Can anything be more degrading than to compel a scientifically trained pharmacist to be the mere medium for the handing over of such a proprietary article? Can anything be more degrading than the spectacle of a duly qualified medical man lowering himself to be the mere exploiter of a puffed and probably over-vaunted preparation? It appears to me that such so-called prescribing is nearly on a par with the dosing that is carried out on those ships which carry a medicine-chest but have no surgeon on board. The bottles of medicine in the chest are duly numbered, and with them is a book describing the symptoms which require a dose of such and such a numbered mixture. Many of you may remember the tale of the ship's steward who went to the captain stating that a sailor had some symptoms which, according to the book, required a dose of No. 9 mixture, but that No. 9 bottle was empty. "That does not matter," said the captain, who in the emergency almost rose to the level of a modern prescriber, "give him equal parts of No. 4 and No. 5."

In connexion with my special department of practice as a physician I am brought in contact with only too many cases of self-drugging by the public, and only too frequently witness the evils arising therefrom. Especially does one see this in connexion with the worship of that absurd fetish, the uric acid diathesis, and the consequent pandering to this modern craze by the unscrupulous vaunters of the many puffed remedies which are warranted to sweep away what is but a natural constituent of the human body. That absurd craze is fostered, if not frequently originated, by the specious advertisements of drugs warranted to cure ills ignorantly, if not falsely, attributed to uric acid. The consequence is that it is now no uncommon sight at a dinner-party to see neurotic young men dropping their lithia tablet into the glass of champagne to counteract what they imagine to be its acidity, lacking as they do both the gastric vigour to deal with the wine and the moral vigour to abstain from it. I venture to sound a note of warning, which I trust may reach beyond these walls to the ear of the public, as to the danger which people incur in dosing themselves with these powerful drugs in tablet form—a danger which is in no sense an imaginary one, since we too often see the pernicious effects resulting from their indiscriminate use, sometimes, alas, when it is too late to remedy the evil results.

And now, gentleman, turning to a more congenial part of my task, let me address a few words of welcome, counsel, and encouragement to those of you who are now entering upon your studies in this school. I address you not only as one who claims and endeavours to be a student still, not only as one who has travelled over the road which you are now about to take, but also as one who from a lengthened experience as a teacher and examiner is well acquainted with the difficulties that you have to overcome, and with the consequent necessity for the courage and application that are required to surmount those difficulties. In the first place, let me heartily congratulate you on your choice of this school, since I am fortunately in a position to testify, from my personal experience, to the high standard of education which is imparted in it, and to the immense benefit in after life which is derived from the course of training here.

[Dr. Luff here discussed methods of study and pointed out the necessity of employing time to the best advantage. He continued:]

But however engrossed you may become in your studies never lose sight of the necessity of carefulness of your health and of the need for daily recreation. The acquisition of knowledge is not the only thing needful. The first requisite to success in life is a healthy body, and the best brain is of little service unless there be sufficient vital energy to work it. Never forget the great value of health as the chief and most important factor in happiness. In primitive times, when muscular power was the chief factor for success in life, the cultivation of the body was the main desideratum, and the cultivation of the mind was almost, if not entirely, neglected. Now the pendulum has swung perhaps too much in the opposite direction, and excessive devotion to mental education has resulted in a corresponding neglect of bodily education. Nothing has pleased me more in watching the development of this school than to witness the establishment of the athletic clubs connected with it, which place the play and recreation of the students on a much more organised footing than they were in my days.

In conclusion, gentlemen, let me beg of you to remember that in joining this school it is your duty to endeavour to maintain its honourable traditions. Each one of you should strive to render himself worthy of the high standard of education that has always been maintained here; each one of you should endeavour to emulate the examples of industry, perseverance, and success that have been set you by so many of your predecessors. When you think of the honourable positions in pharmacy that have been reached by so many past students of this school, when you recall the names of such men as Bentley, Attfield, Carteighe, Hanbury, Hills, Martindale, Allen, Umney, Greenish, and Squire, surely with such examples of successful work and perseverance you should have the strongest stimulus to follow their examples and also, I trust, to achieve their deserved success.

## A CASE OF ACROMEGALY.

By J. PIRIE, M.A., M.D. ABERD.

THE patient, a married woman, aged 43 years, was seen by me in September, 1898, when the following notes were made. She has resided in a village in Warwickshire for the last 25 years. She has borne six children, five boys and one girl. One boy died a few hours after premature birth; the daughter died about four years previously at the age of 17 years after suffering for some months from anorexia nervosa. The surviving children are healthy. There is nothing else of special interest in the family history. The disease first manifested itself in 1886, when menstruation finally ceased. Pains and paræsthesia of the arms and legs were felt and the patient noticed that her hands and feet were getting larger and more awkward. The sight of the left eye began to fail and she suffered much from painful headaches and neuralgic pains in the left eyeball. Her friends perceived at the same time an alteration in her features, which became more uncouth, while a perceptible enlargement of the nose, chin, and ears occurred. Twelve months after the first appearance of the symptoms her last child was born. Sternberg remarks that no woman suffering from amenorrhœa and acromegaly has ever been known to conceive. In this case, however,

there is the distinct history of conception occurring quite three months after the onset of amenorrhœa and other symptoms of acromegaly. The cessation of menstruation is usually one of the earliest manifestations in acromegaly, and Sternberg puts it down as due to the ovaries. Along with the development of physical symptoms a peculiar alteration of the mental condition took place. Attacks of narcolepsy overcame her, she became sluggish and irritable, and she suffered much from the *ennui* of life. Of late years, however, she improved in this respect, and she is now extremely patient and even cheerful. After her confinement she suffered for four years from galactorrhœa.

The patient first came under my notice about five years previously when she presented most of the classical features of the complaint. She suffered much at this time from polydipsia and glycosuria, and for over 12 months there was an almost constant dribbling of saliva from the mouth. There is now a marked abatement in both these symptoms. Such a remission is frequently remarked in acromegaly—e.g., by Valat<sup>1</sup> and by Rolleston.<sup>2</sup> The thyroid was greatly enlarged, but under treatment with thyroid gland substance it diminished much in size. The condition of the skin and nails was also improved by this treatment. Despite the awkwardness of the hands and the clumsiness and increasing feebleness of the legs she was, until 15 months ago, able to get about and to attend to a limited extent to her household duties. She was also capable of a little knitting and needlework. Gradually increased difficulty in walking was noticed and she complained that she could not lift her right leg along. In going upstairs she had to lay hold of the banisters and pull herself up step by step. She could not rise from her chair unless she had something to lay hold of. Breathlessness on the slightest exertion appeared and ultimately the muscle weariness so gained upon her that she had to take entirely to bed.

Her present condition (i.e., in September, 1898) is as follows. With regard to the head and face (Fig. 1) the features are very uncouth and the facial expression is dull and heavy. The nose, lips, tongue, and the external parts of the ear are greatly enlarged. The face is of the usual "type ovoïde" described by Marie. The lower jaw is lengthened and hypertrophied, while the alveolar process projects in front of the upper jaw. The chin is very prominent and so are the zygomas. The head is brachycephalic and very similar to that of the anthropoid apes; the facial angle is small and the hypertrophied lower jaw protrudes in front of the perpendicular of the forehead (prognathism). The circumference of the skull measures only 21 inches. (Cases are, however, recorded in which the skull is found very large. Signorini and Caporiacco mention a case in which it measured 24 inches,<sup>3</sup> and in a case recorded by Schultze it measured as much as 26 inches.<sup>4</sup>) The soft parts are remarkably changed as well as the bones. The scalp is much thickened, as is also the skin of the face. The natural lines of the face are very deep and furrowed. The neck is thick and short and the head is sunk in between the shoulders, due to the spine being curved in the lower cervical and upper dorsal regions (cervico-dorsal kyphosis). The cartilages of the larynx are hypertrophied. The lymphatic glands are enlarged. Large swellings are felt on the site of the parotid and submaxillary glands. Goitre is present. In addition to the kyphosis there is a compensatory lumbar lordosis and also a certain degree of scoliosis. The clavicles are enormously hypertrophied. The ribs are thickened and expanded, the costal cartilages feel bony, and there are nodular projections resembling the "rachitic chaplet" at the junctions of the ribs and their cartilages. The sternum is broad and massive. The ensiform cartilage protrudes markedly and there is the characteristic "double bosse" of the sternum due to the falling away of the whole bone obliquely forwards towards the perpendicular. (Brigidi<sup>5</sup> and Fritsche-Klebs<sup>6</sup> made special note of the "double bosse" of the sternum in acromegaly.) The thorax moves little in respiration, which is chiefly abdominal, its lower diameter is increased, and it is flattened laterally. The spine, acromion, and coracoid process of the scapula are all hypertrophied. The increase in the breadth and thickness of the hands and feet is very marked,

<sup>6</sup> Klinische und Pathologisch-Anatomische Untersuchungen, Leipzig, 1884.

especially in contrast with the comparatively slender fore-arms and legs. The hands belong to the "type en large" of Marie, there being no increase in the length as occurs in the other type he notes—viz., the "type en long" or "type géant." The fingers are thick, massive, and stumpy, like "little sausages" (P. Marie). The

FIG. 1.

Showing general appearance of the patient.

lines in the palm and about the interphalangeal joints are deeply marked. The nails are broader than they are long and show longitudinal striation. The feet are of gigantic size, with thick coarse toes (Fig. 2). The condyles of the lower end of the humerus are enlarged and thicknesses are to be felt around the head of the humerus. The head of the fibula, the upper extremity of the tibia, the patella, the condyles, and the great trochanter of the femur are all enlarged. The skin is thickened and easily thrown into folds. Its chromatogenous functions are disturbed, much as in rheumatoid arthritis. Small freckles are frequent; patches of a yellowish bronzing occur also on the face, the chest, and the insides of the thighs. (Motais<sup>7</sup> describes a bronzing such as occurs in Addison's disease.) Numerous small warts are present. (Mollusca fibrosa are described in many cases and xanthemalike tumours by Dallemagne.<sup>8</sup>) The patient suffers from a brownish seborrhœa, especially troublesome in the scalp. The hair is thick and coarse and stands straight upwards. There is a scanty beard and moustache. Profuse perspirations are constantly complained of. The heart is dilated. There is tachycarditis, the heart beating about 98 to the minute. A soft systolic basic murmur is heard at times. Palpitations and fainting fits occur very often. Dyspnoea is marked and asthmatic-like attacks occur during which the patient has to sit up in bed and fight for her breath. There are no oedema, no signs of atheroma, no varicose veins, and no hæmorrhoids. A slight

degree of cyanosis is noticed. Retro-sternal dulness can be distinctly made out on percussion. (Erb describes a cup-shaped dulness over the upper part of the sternum, considered by him to be due to enlarged thymus. This is, however, disproved, the dulness being due to the thickening of the manubrium and the ribs.) The patient's speech is drawling and her voice is hoarse and low. The mucous membrane of the palate and all the lymphatic structures of the pharynx and the tonsils are greatly enlarged. The appetite is always large and at times ravenous. Polydipsia has been a prominent symptom, but is not so now. There is great constipation. Attacks of "bilious vomiting" occur, which are accompanied by severe cramp-like pains. The liver and splenic dulness extend far beyond their usual limits. The enlargement of these two organs may be put down to splanchnomegaly, which is an exceedingly rare phenomenon save in acromegaly. The urine is abundant and generally very pale. Occasionally a deposit of calcareous phosphates has been noticed. No albumin or sugar is present now, though sugar has been found in varying amounts during the past five years.

The vagina is capacious; the uterus is diminished in size, as measured by the uterine sound. The clitoris is hypertrophied. Muscular atrophy is a prominent feature, affecting the thenar, hypothenar, and interossei muscles of the hands, the forearm and arm muscles, the calf and thigh muscles, and also the glutei. The scapular muscles are wasted, but otherwise the muscles of the trunk are not affected. The circumference of the forearm at the middle is eight inches, of the arm seven and three-quarter inches, of the calf 10 inches, and of the thigh 15 inches. (Duchessau<sup>9</sup> has

FIG. 2.

Showing enlargement of the feet.

made a special study of the atrophy of muscles in acromegaly. So marked is it in some cases that it has been mistaken for syringomyelia, progressive muscular atrophy, or amyotrophic lateral sclerosis; it has also been mistaken for Charcot's cervicalis pachymeningitis hypertrophica and for erythromelalgia.)

With regard to the organs of special senses, the skin of the eyelids is thickened and puffy. The lacrymal glands are hypertrophied. Increased lacrymation occurs at times and I have noticed a colloid-like secretion between the eyelids.

<sup>7</sup> Progrès Médical, 1891, p. 413.

<sup>8</sup> Archives de Médecine Expérimentale et d'Anatomie Pathologique, vii., 1895, p. 589.

<sup>9</sup> Thèse de Lyon, 1891.

Slight exophthalmos is present and there is a moderate degree of ptosis of the upper eyelid of the left eye. Supra-orbital neuralgia and shooting pains in the left eyelid are complained of. There is amblyopia, nearly complete in the left eye, and colour vision for blues and yellows is defective. Bi-temporal hæmianopsia is present. The pupils contract in accommodation and react to light, though very sluggishly in the case of the left eye. With the ophthalmoscope optic atrophy is found. With the exception of ptosis in the left upper lid there is no paralysis or paresis of the muscles supplied by the oculo-motor nerves. There is no anosmia and no perversion of the sense of taste. Hearing is good but tinnitus aurium is complained of. Sensory disturbances are marked. Shooting pains in combination with paræsthesia, tingling, and numbness are complained of in the arms and legs. Neuralgic pains are felt also in various parts of the body—viz., the face, chest, back, and loins. A remarkable perversion of thermic sensibility is found in the lower limbs and over the front of the abdomen and chest up to about the level of the fourth rib, the patient having no sensation of heat in these regions. Mustard blisters applied over the abdomen or to the lower extremities are not felt at all, even if left on long enough to blister. There is no ataxia and she can accurately tell the position of her limbs. The right patellar reflex seems somewhat diminished. She has never lost control of the urine or fæces. Sternberg remarks particularly on the occurrence of pain and paræsthesia as valuable signs for diagnosis in the early stages of the disease; they are probably due, he considers, to changes in the cutaneous nerves.

As to treatment, I have found antikanmia to give most relief from the pains and headaches. The usual remedies—phenacetin, antipyrin, exalgin, &c.—had no effect. The use of thyroid gland substance gave a certain improvement, but it had to be stopped because of the pain and diarrhoea it produced.

*Note.*—Since the above notes were written the patient died quite suddenly, and unfortunately a post-mortem examination was refused.

Harbury, Leamington Spa.

## MORVAN'S DISEASE (?) OR LEPROSY.

By D. DOUGLAS-CRAWFORD, M.B. EDIN., F.R.C.S. ENG.,  
HONORARY SURGEON TO THE LIVERPOOL STANLEY HOSPITAL.

THE condition known as "Morvan's disease" or "panaritium analgicum" was first described by Morvan of Brittany in 1883. Since that date notes of many cases have appeared in continental journals, but it was not till 10 years later that Pringle of Glasgow reported what was apparently the first case in this country.

The clinical features of the disease are such that Charcot regarded it as a form of syringomyelia, while Morvan has strenuously fought for a recognition of the condition as a distinct disease. Bastian also regards it as a variety of syringomyelia, the onset usually occurring between the ages of 15 and 20 years and rarely as late as the thirtieth year, when a gliomatosis commences in the cord without any assignable cause around a congenitally enlarged central canal. An excellent description of a necropsy is given by Gimball. He found a diffuse sclerosis of the peripheral nerves and posterior columns and horns of the cord in the cervical enlargement; the central canal was distended, and in some sections cavities were found in the position of the posterior horns.

In 1897 Jeanselme<sup>1</sup> showed two cases of this disease, one of which was undoubtedly associated with leprosy, and in the other there was possibly a leprosy infection. In the same year Zambaco Pasha, at the Leprosy Congress held in Berlin, gave it as his opinion that Morvan's disease was simply leprosy modified by climate, hygiene, and environment—in short, an attenuated form. He was supported in this view by Falcão of Lisbon, García de Coli of Columbia, and others. Zambaco considered that the absence of the bacillus lepræ did not exclude leprosy, for such a diagnosis was of necessity first based upon clinical signs. Jeanselme having recognised the possibility of both diseases existing together, and of one condition being mistaken for

the other, compared the two cases above described with a number of cases of Morvan's disease collected in Brittany, and from the comparison concluded that there were certain clinical signs which distinguished one disease from the other. He pointed out that in the Morvan type of syringomyelia whitlows are often limited to the hands, while in leprosy they attack both fingers and toes; anæsthetic areas are characteristic and facial paralysis is rare and of central origin in Morvan's disease, whereas in leprosy the anæsthesia affects both the upper and the lower limbs, and the face and trunk partially, and facial paralysis is frequent and peripheral in origin; again, in Morvan's disease the ulnar nerves are normal and never nodose, the reflexes are exaggerated, and scoliosis is often present, while in leprosy the ulnar nerves are nodose, the reflexes are normal or absent, and there is no scoliosis.

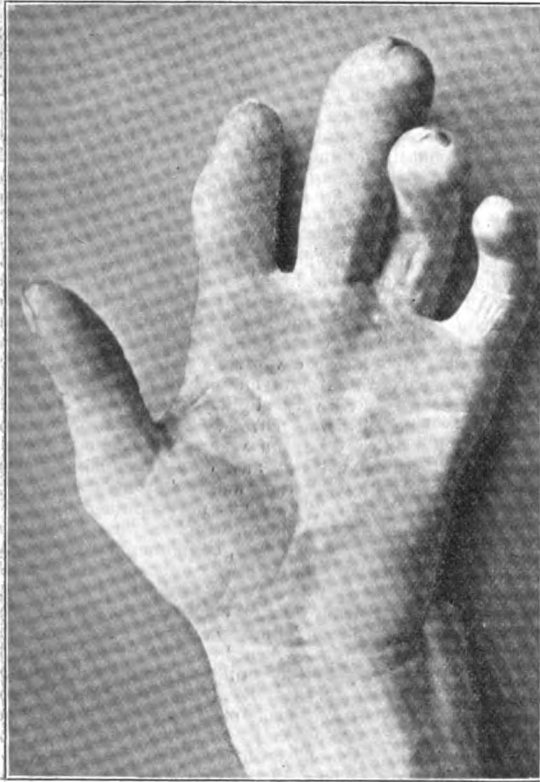

A man, aged 27 years, was placed under my care at the Liverpool Stanley Hospital by Mr. J. W. Hudson of Millom on May 8th, 1900. Five years before he had worked in a lime-quarry, but owing to the appearance of fissures in both palms, which he said penetrated to the bone and which he attributed to the lime, he changed his occupation and became a railway labourer for the next six months. The fissures, however, still persisted, so he returned to the quarry and worked there intermittently until Nov. 6th, 1899. Two years before whitlows began to form on the fingers of both hands but occasioned no pain. A whitlow started as a small pimple on the pulp of the terminal phalanx; it became very painful, although the digit was numb and cold. As the whitlow formed the pain subsided, and subsequently a piece of bone came away and the wound healed. The whitlows appeared in a definite order, first on the right index; secondly, on the left index; thirdly, on the left ring finger (the right ring finger still remaining unaffected); fourthly, on the right middle finger; and fifthly, on the left middle finger. The swelling of the right shoulder occurred two or three weeks after the whitlow on the right middle finger had healed; the whole arm suddenly became swollen, and when the swelling subsided the joint was left in very much the condition that it was found to be on admission. Four years before the patient had been first seized with what he described as "sweating spells" which had become more frequent since November, 1899. The attack lasted for about half an hour, during which time the patient sweated profusely and was only partially conscious. The sweating ceased as suddenly as it commenced and then the patient felt quite well. The family history presented no unusual feature and the patient enjoyed excellent health until the onset of this disease. He had always resided in this country; there was no evidence of syphilis and no history of an injury. The patient had married about 14 months before.

On admission the patient's right shoulder-joint was found to be greatly enlarged and fluctuating. There were signs of old incisions on the outer side; the joint had been opened five times, each time with great relief to the patient, but it rapidly refilled. The head of the humerus projected under the coracoid, movement of the joint was limited, the bones grating upon each other, and the origin of the long head of the biceps had been destroyed. The digits of both hands showed signs of mutilation, but the thumbs, the little fingers, and the right ring finger had not suffered. As regarded the nervous system, speech was slightly indistinct and slurred, but the taste was unimpaired. The patient could protrude his tongue, but could not move it laterally. The pupils reacted to light and accommodation, there was no limitation of the field of vision, and no nystagmus. There was right external strabismus of many years' standing. If the patient closed his eyes while standing up he toppled over. The muscles of the left thumb were slightly wasted. Sensation to pain, heat, and cold was greatly impaired over the skin of those digits which were supplied by the median nerve. The other skin areas were fairly normal. Tactile sensation was normal throughout both limbs; the muscular sense was unimpaired, but a tremor of the limbs was noticeable on attempts being made to use them. The knee-jerks were exaggerated, the plantar reflex was present, and ankle clonus was well marked. The gait was slightly spastic. Sensation to pain, heat, and cold was impaired over the outer sides of the upper thirds of both thighs and also over the dorsal surfaces of the feet. Sensation in the cervical region was normal except over the area supplied by the right small occipital nerve.

Ten days after admission the left middle finger became

<sup>1</sup> Société Médicale des Hôpitaux de Paris, July 30th, 1897.

greatly swollen. It was incised (the incision being absolutely painless) and a little weak pus escaped; the wound healed readily. On May 26th the right shoulder-joint was incised and discharged a pale watery fluid—this continued to flow for three weeks, when the wound healed; the patient left the hospital on June 23rd. While in the hospital he suffered from one of the "sweating" attacks. He felt unwell in the forenoon of June 17th and he was sent to bed; his temperature rose to 103° F., but

Left hand of patient, showing mutilation of fingers.

dropped again to normal in a couple of hours; during that time he sweated profusely and appeared to be dazed and stupid. A year later (in July, 1901) the disease showed no signs of advance; the patient only interrupted his work when the shoulder-joint became so distended as to need aspirating, and even then it was only for a few days.

Previously to the Berlin Leprosy Congress of 1897 this case would certainly have been classified as one of Morvan's disease; in that year Zambaco and others refused to recognise Morvan's disease as any other than leprosy modified by environment and other circumstances. Jeanselme, however, considers that they are two distinct diseases,<sup>2</sup> and my case would very clearly answer to the definite distinguishing signs of Morvan's disease which he has laid down; in it the nerves were not nodose, the reflexes were exaggerated, whitlows were limited to the fingers, and the hydrarthrosis of the shoulder was suggestive of the disease. There was, however, no scoliosis. The case is interesting, but whether a distinction is to be drawn between leprosy and Morvan's disease or not can only be decided when the pathology of leprosy is more thoroughly worked out than at present.

## AN INTERESTING CASE OF COMPRESSION.

By EUGENE J. O'MEARA, L.S.A.,  
CAPTAIN, I.M.S.; OFFICIATING MEDICAL OFFICER, 11TH P.W.O.  
BENGAL LANCERS.

A SOWAR of the 11th Bengal Lancers, aged 26 years, was admitted into the Regimental Hospital at Meean Meer on the morning of March 27th, 1901, with the following history. On the previous afternoon about three o'clock he had fought with another man at the canal bridge and had received several blows from a rather heavy stick about the body and the head. After the fight, however, he went on a distance of two miles to some fields, where he remained cutting *khesil* for about four hours, returning to the bridge in the evening about 7.30, when he got off his mule, as stated by the other men, to micturate, but feeling a pain in the head he sat down on the canal bank and from that moment apparently remembered nothing further. The other men, thinking that he was following, went on and left him. Next morning he was found by a search party lying exactly in the same place in a state of stupor, but able to name the man in charge of the party and also to give his own name.

On admission into the hospital about 10 A.M. his condition had improved, for he was able to make a very fairly clear statement about the fight before the adjutant and myself. But after 1 P.M. the patient became rapidly worse and at 4 P.M. the condition was as follows. The pulse was slow, regular, and heaving, the pupils were widely dilated and did not react to light, and there was retention of urine. The condition of the muscles on the two sides was practically the same, paresis perhaps being more marked on the left side. There was practically no difference in the surface temperature of the two sides. The patient was quite comatose. On careful examination of the head no evidence of a depressed fracture could be discovered, the only external sign of injury on the head being a very slight redness over the left temple. Subcranial hæmorrhage was diagnosed and I at once proceeded to operate.

Very little chloroform was given and that more for appearance's sake before natives than on account of necessity, as the patient was quite comatose. The usual horseshoe-shaped flap was turned down and the trephine was applied over the anterior branch of the right middle meningeal artery. On removing the bone a large amount of very dark clot protruded through the trephine hole, but the artery was quite uninjured. The trephine was now applied over the posterior branch of the middle meningeal artery, as the hæmorrhage was very profuse and appeared to be coming up from the direction of this branch, but the bone having been removed the artery was again found to be intact. The hæmorrhage was now excessive and was dark venous in character, the patient's condition being very critical. Having rapidly enlarged the posterior trephine hole and passed my finger backwards into the occipital region it was at once evident that the whole of the posterior part of the brain was very much compressed by an enormous clot. Five and a half ounces of clot were quickly removed with the spoon, the brain expanding as the clot was turned out. At the same time long strips of gauze were rapidly passed into the cranium between the bone and the dura mater, the ends being brought outside, the objects being as follows—(1) to act as a drain for the hæmorrhage and (2) to minimise as far as possible the danger of spreading œdema from a too sudden expansion of such a compressed brain. The trephine discs were replaced as accurately as the gauze drains would allow and the flap was partly sutured round its anterior part, but the posterior portion, together with the subsequent incisions, were left entirely open for the gauze drainage. A very large dressing having been applied the patient was kept lying absolutely still on his right side to facilitate the blood drainage. The pulse improved immediately and at 10.30 P.M. the patient was conscious and able to speak one or two words.

During the first 36 hours after the operation hæmorrhage continued and soaked through the dressings four times, but after this time it appeared to stop suddenly and there was none at the end of 48 hours. On April 1st I removed very gradually and with great care the gauze drains from inside the cranium; there was no sign of any further hæmorrhage. The posterior edges of the horseshoe flap and

the other incisions were now drawn together with wire sutures. On the 5th the temperature had never been above normal since the operation. There was no pain, headache, or sleeplessness. On this date I handed over the case to the charge of Captain W. H. Ogilvie, I.M.S., as I was ordered home on sick leave.

The following is an abstract of Captain Ogilvie's subsequent notes. On April 10th the anterior part of the flap had healed and the posterior part was healing. The patient's condition was excellent. The temperature was normal. On the 15th all the stitches were removed. The general condition was the same. On the 30th the posterior edges of the flap had healed with the exception of a sinus. On May 6th, on probing the above-mentioned sinus dead bone was discovered. The sinus having been opened up it was found necessary to remove the posterior trephine button. On the 17th the wound had nearly healed, but a small sinus remained leading down to bare bone. On again opening up the sinus the upper margin of the posterior trephine hole was found to be rough, but there was no actual necrosis and no bone was removed. On the 23rd this wound had almost entirely healed, when the soft parts sinking somewhat into the trephine hole caused it to drag open again. On the 31st the wound had very nearly healed again: there was no sinus or discharge. On June 2nd the case was handed over to Lieutenant McCarrison, I.M.S. On the 4th the wound had quite healed and the patient was recommended for two months' sick leave to recover his strength before returning to duty. On the 12th the patient was discharged from hospital as recovery was complete. There was no evidence of any cortical irritation and the motor system, the special senses, and the mental condition were unimpaired.

I have recorded the above case as there are many interesting points, especially as regards the history and the extraordinary length of time before definite symptoms of compression appeared and the absence of any very definite symptoms to enable the seat of injury to be localised. Also I have not been able to trace any other case in which plugs have been successfully used in the extra-dural space with the objects of: (1) acting as drains for the excessive hæmorrhage, it being impossible to localise or to reach the bleeding point (and I think there is undoubted evidence in this case at least to show that they acted admirably); and (2) to exert some pressure on the expanding brain. In this case the compression was so great, and extended over such a large area of the brain surface, that *a priori* it is very doubtful whether without some means of this kind the patient would have escaped the danger of spreading œdema. What the value of the treatment may be I leave to others more competent to judge. It was a sudden idea which occurred to me as a last resource to save the patient's life, and I feel confident that without the plugs I should never have succeeded in bringing the case to a successful issue.

### A CASE OF SUDDEN DEATH EIGHT DAYS AFTER AMPUTATION OF THE FOREARM.

By P. N. GERRARD, M.D., B.Ch. Dub.,  
DISTRICT SURGEON, VLU SELANGOR, FEDERATED MALAY STATES.

A CHINESE coolie, aged 36 years, was admitted into the District Hospital, Kwalu Kubu, on August 14th, 1899, suffering from disorganisation of the right hand which was the result of an accident in blasting with dynamite. The man, who had travelled through from Raub Pahang, about 50 miles, in a bullock-cart, arrived in hospital four days after his accident. The wounds were septic on admission, and he had a temperature of 100.8° F. He was a moderately well-developed man and an opium-smoker. On examining the remains of his hand all the bones of the metacarpus were protruding and blackened, the thumb and little finger only remaining attached to the arm, the wrist-joint was inflamed and swollen, the lymphatic glands were enlarged, and a lymphatic cord could be traced from the elbow to one or two enlarged glands in the axilla. In consideration of the inflamed wrist-joint and the man's general condition I deemed it advisable to operate fairly high up, and so performed a modified circular amputation, dividing the bones at the middle of the forearm. The operation was completely

successful and was uneventful, the patient recovering well from the chloroform. His temperature, which was 102.6° on the table, began to fall nicely after the evening of removal of the mangled part. A slight amount of pus formed beneath the flaps, owing, I presume, to the infected lymphatics, and the wound was syringed out twice daily. Granulation proceeded; the tube had to be shortened about every second day. The patient began to feed well and to move about the ward on the fifth day (without permission). The temperature gave every promise of an exceedingly good result, when on the evening of the thirteenth day (eight days after the operation) I received an urgent note from the dresser on duty to say that the patient had got "a fit" and was very bad. I was in the hospital within five minutes of the receipt of the note, only to find the patient dead. The history of his attack was as follows. The patient had been lively and in good spirits all day. At 6.25 P.M. the dresser placed the thermometer under his arm as he sat up in bed, and just as the thermometer was removed, registering 99°, he fell back gasping for about five minutes and died just before my arrival at 6.40. The patient was given whisky, but so rapid was the seizure that there was no time for the exhibition of other remedies.

**Necropsy.**—A post-mortem examination was made 12 hours after death. Superficially nothing worthy of note was seen. On examining the lungs the lower lobe of the left lung was found to be deeply congested. The heart was normal in size and shape and the left side contained a small amount of fluid blood; the right auricle contained a long thin ante-mortem clot which extended into the ventricle: the clot was about four inches long by a quarter of an inch at its broadest part. The tricuspid valve was very slightly thickened, also the mitral valve. The aorta was normal. The heart and lungs were removed *en masse* and the vessels were traced out to their smallest calibre without any clot or embolus being found. No other post-mortem manifestations worthy of comment were found. The brain was not examined.

The cause of death in this case, which at first sight was diagnosed, and, I think, with reason, as pulmonary embolism, is peculiar from the fact that notwithstanding very careful search no clot or embolus was found in any part of the lungs. The fact that the patient did not complain of any palpitation or distress until a few minutes before dissolution, when he remarked before falling back in his bed that his "breathing was difficult," considered in connexion with the finding of a clot (small in diameter) partly in the right auricle and extending into the ventricle, leads me to the conclusion that the immediate cause of death was cardiac syncope consequent on the disturbance of an ante-mortem clot which had formed in the right auricle, as a result of septicæmia from which at the date of his death he had recovered—or, in other words, he died from cardiac thrombosis. It furthermore raises the question as to the advisability of exhibiting alcohol fairly freely in all cases where operations cannot be done promptly, and where septic absorption is probable, in order that no slowing of the circulation and consequently no deposition of fibrin may take place in the right auricle. This case is of interest, I think, from the similarity of the symptoms to pulmonary thrombosis or embolism.

Vlu Selangor.

**DEATH OF A CENTENARIAN.**—The Algiers correspondent of the *Petit Journal* states that an Arab woman named Aicha Khellafia-bent-Mohamed died at Blida on Sept. 24th, at the age of 110 years. From an examination of various documents, including title-deeds of property, it appeared that she was born in the year 1791. Her mind was quite clear and she used to relate anecdotes of the earthquake of 1825 by which Blida was overwhelmed. She said that she was already a grandmother when the French took possession of Algeria and occupied Blida.

**WIGAN MEDICAL SOCIETY.**—A meeting of this society was held on Sept. 26th, Mr. William Latham (the President) being in the chair.—It was resolved to vote a sum of money for the publication of a catalogue of the medical works in the reference department of the Wigan Free Library, each member to receive a copy.—Dr. Arthur J. Wallace, assistant lecturer on midwifery and gynaecology in University College, Liverpool, read a paper on Some Lesser Gynaecological Ailments.—An interesting discussion followed in which the following members took part: the President, Mr. T. M. Angior, Dr. J. Blair, Dr. F. Rees, Mr. M. G. McElligott, Dr. R. P. White, and Mr. C. M. Brady.—Dr. Wallace replied.

# PHYSIOLOGICAL PHENOMENA PRECEDING OR ACCOMPANYING MENSTRUATION, TOGETHER WITH NOTES ON THE NORMAL TEMPERATURE OF WOMEN.

By HELEN MACMURCHY, M.D.,

RESIDENT MEDICAL ASSISTANT, TORONTO GENERAL HOSPITAL.

There is no physiological condition so nearly resembling disease as that which produces every month in an adult woman a change so profound that it has been looked upon as the expression of a morbid condition.—GUERIN.

THE true significance of menstruation still remains among the unsolved problems of medicine, and was mentioned among the most pressing of these problems by Dr. Milne Murray in a recent presidential address before the Obstetrical Society of Edinburgh. We must look primarily to physiology for a solution of this problem and it is encouraging that some progress has been made in this direction in the last year of the nineteenth century, when it was proved that so far as metabolism is concerned vicarious action exists between the ovary and the thymus gland. Many of the physiological phenomena of menstruation have been observed from the dawn of medical science, but it is probable that some still remain unrecognised and undescribed. Women in the possession of perfect health need to pay little attention to the advent of that menstrual epoch on or about the twenty-eighth day which makes itself such a dreaded event to others. It is a remarkable fact that phenomena appear regularly for many years and yet pass unnoticed because they are supposed to occur in everyone and are therefore considered of no importance. Besides, few persons are born observers and what the profession have not seen the laity are not always able to bring to their notice. Among known phenomena are: neuralgia (King); disinclination for society (Dalton); weariness and pain in the back and in the limbs (McKendrick); general malaise and irritability of temper (Pozzi and others); headache, nausea, and leucorrhœa following menstruation (Garrett); increase of pigmentation, the complexion dull or sallow, and black rings round the eyes (Barnes); diminution of the production of urea more than 20 per cent during menstruation, slower pulse, and a fall of at least 1 per cent. in temperature (Rabuteau); the discharge anterior to the flow of a quantity of vaginal mucus, brown and rusty in colour and probably of a peculiar odour (Flint); tension in the region of the uterus and ovaries, which are sensitive to pressure, alternate feeling of heat and cold, slight increase in temperature of the skin, retardation in the process of digestion, and variation in the secretion of sweat (Landois and Stirling); and vertigo, herpes, parotitis, pruritus vulvæ, flashes of heat, swelling of the thyroid gland, increased frequency of urination, painful swelling of the mammae, changes in individual character, angina of menstruation, and a form of subacute tonsillitis (Cushing and Cumston in the Twentieth Century Medicine). Longuet also gives one instance of periodical enlargement of the thyroid gland during menstruation. Barnes's well-known cases of hernia of the left ovary, in which the sphygmograph applied to the herniated ovary showed a high blood-pressure preceding menstruation, has been frequently referred to, and there is also an interesting case reported in the Transactions of the Edinburgh Obstetrical Society, February, 1893, which bears on the same point. Dr. Young there gives notes of the case of a patient, otherwise healthy, aged 29 years, who at the menstrual period suffered from a headache so severe that she could not lift up her head and was unfitted for duty for several days. The sphygmograph record showed a high blood-pressure. Dr. Young then removed during menstruation 10 ounces of blood by venesection and this gave instant relief. The operation was again performed shortly before another menstrual period and several months thereafter the patient reported herself as being as well as could be desired. M. Cautier before the Académie de Médecine at Paris in 1900 also mentioned that the approach of menstruation may be recognised by changes in the hair. Flint<sup>1</sup> refers at length in the following passage to the evolution of carbonic acid in the female:—

*Exhalation of CO<sub>2</sub>.—Influence of Sex.*—All observers have found a marked difference between the sexes, in favour of the male, in the proportion of CO<sub>2</sub> exhaled. Andral and Cavarret noted an absolute

difference of about 45 cubic inches per hour, but did not take into consideration the differences in the weight of the body. Scharling, taking the proportion exhaled to the weight of the body noted a marked difference in favour of the male. The difference in the degree of muscular activity in the sexes is sufficient to account for the greater evolution of CO<sub>2</sub> in the male, for this principle is exhaled in proportion to the muscular development of the individual, but there is an important difference connected with the variations with age which depend upon the condition of the generative system of the female. The absolute increase in the evolution of CO<sub>2</sub> with age in the female is arrested at the time of puberty and remains stationary during the entire menstrual period, provided the menstrual flow occur with regularity. During this time the average exhalation per hour is 714 cubic inches. After the cessation of the menses the quantity gradually increases, until at the age of 60 it amounts to 960 cubic inches per hour. From the age of 60 to 82 the quantity diminishes to 793 cubic inches, and finally to 670 cubic inches. When the menses are suppressed there is an increase in the exhalation of CO<sub>2</sub> which continues until the flow becomes re-established. In a case of pregnancy observed by Scharling the exhalation was increased to about 885 cubic inches.

Quantity of CO<sub>2</sub> Exhaled by the Male.

Dr. Engelmann of Boston, in a recent article entitled "What is Normal Menstruation?"<sup>2</sup> gives statistics concerning 5000 women most of whom were in school or college or employed in departmental stores and about the age of from 18 to 22 years. Dr. Engelmann found that in 24 per cent. of these menstruation occurs at intervals of less than 28 days, in 31 per cent. at intervals of 28 days, and in 45 per cent. at intervals of more than 28 days. From 66 to 70 per cent. suffer more or less pain during menstruation; this number varies with age and intensity of occupation. Dr. Jacobi finds about 65 per cent. suffer more or less and De Boismont (quoted by Dr. Jacobi) finds that 77 per cent. have more or less pain. Pain, however, can hardly be considered physiological and is therefore not included in the present inquiry. There are also variations described in pulse-rate, production of urea, and temperature, which are referred to later under the head of "Temperature." With the exception of parotitis, swelling of the thyroid gland, and the excretion of CO<sub>2</sub> the phenomena mentioned and a few others to be presently described have been investigated in 100 cases, the results of which are submitted herewith.

In regard to the production of urea a few experiments made under the direction of the assistant in chemistry at the chemical laboratory of the University of Toronto confirm the results referred to hereafter, as do also a few observations on pulse-rate and blood-pressure. The phenomena of which no description is given in literature to which the writer has had access are: loss of sleep; a tendency to pessimism and mental depression; disturbances of the special senses; cutaneous hyperæsthesia; a tendency to constipation or diarrhœa; a great tendency to "take cold," as shown by frequent attacks of coryza, occurring in some women at every menstrual epoch; a feeling that any work in hand must be all "finished up" (a feeling as if you could not do enough); and letting things fall or "slip through the fingers" in some unaccountable manner.

On Nov. 29th, 1900, 150 temperature charts, and 150 copies of the following list of questions, each accompanied by a letter of explanation, were sent to the nurses and graduates of Toronto General Hospital Training School for Nurses by the kind permission of the superintendent. Twenty-two of the answer papers were returned filled up. At the end of March, 1901, 150 additional copies of the questions were sent to the nurses of St. Michael's Hospital (by kind permission) to the students of the Women's Medical College and other colleges, and to several women physicians in practice in Toronto, as well as to a number of women teaching in the Toronto Public Schools. Sixty-eight replies were returned, and the additional papers required to make up 100 were then easily secured, most of the replies being dictated. All those answering the questions were well enough to do a hard day's work, and almost all of them were less than 30 years of age, few or none being married. The questions were as follows:—

Besides the well-known phenomena of menstruation, such as hæmorrhage, slight mammary changes, weariness and lassitude, sensations of pressure and pain in the pelvis, &c., are any of the following symptoms

<sup>1</sup> Human Physiology, pp. 147 and 148.

<sup>2</sup> New York Medical Journal.

present, say, from the twenty-first to the twenty-eighth days?—  
 1. Disturbed sleep. For example: Are you more wakeful than usual?  
 2. Vertigo. 3. Headache. 4. Neuralgia. 5. Mental depression. Is there any change in your feelings? Do you prefer being alone?  
 6. Increased nervous energy, feeling you must "finish up" everything.  
 7. Lessened nervous or muscular power. Do you let fall things you are holding or carrying? 8. Cutaneous hyperæsthesia, feeling as if clothes irritated the skin. 9. Vaso-motor disturbances, flashes of heat and cold. 10. Digestive disturbances—flatulence, &c. 11. Constipation. 12. Diarrhœa. 13. An increased quantity of urine. 14. Cutaneous eruptions. If so, where (lips, face, chest, &c.)? Of what character (vesicles, pustules, acne, herpes)? 15. Disturbances of the special senses. Is the sense of smell more acute? Are you eyes more easily tired? 16. Subacute tonsillitis. Any tendency to sore-throat? 17. Do you take cold more easily? 18. Differences in pigmentation. Is the complexion dull or sallow? Are there rings round the eyes? 19. Are there changes in the hair? Is it dull, harsh, wiry, or less glossy? 20. Is there an irritating watery discharge before the discharge of blood? 21. Is there an irritating watery discharge after the discharge of blood?

Please qualify your answer, if affirmative, by the words "occasionally," "frequently," "generally," "always." If any of the above symptoms occur at any other time than from the twenty-first to the twenty-eighth days please mention the time. Are there any other phenomena which you can suggest for observation?

#### Summary of Answers.

Question.	No answer.	"No."	"Yes."	"Occasionally."	"Generally."	"Frequently."	"Always."

**Notes on individual replies to the questions in numerical order.**—1. One hardly sleeps at all the first night of menstruation. Three sleep more heavily than at other times. Two specially mention dreams at this time. 4. One reports sciatica. 5. Six specially mention irritability, one writing as follows: "I find that I am more easily provoked by small annoyances. Loss of patience is the chief difference." 6. One reports that the "feeling as if you couldn't do enough" comes after menstruation is over. 7. This condition (lessened nervous or muscular power) is very marked in some cases. One mentions that great domestic inconvenience is caused by many dishes being thus broken by one who shows this phenomenon markedly. 10. Apparently some articles of diet, especially fish, cannot be easily digested at this time. 13. One reports the quantity of urine as being diminished. 14. A large number report eruptions on the face, lips, and chest, especially on the face. Probably those on the chest and shoulders often escape observation—they frequently resemble petechiæ. Two report "red spots seldom coming to a head." One reports roughness of the skin in small spots on the face and another describes what is probably the same phenomenon as "shell-corn" on the face. (Dr. Goodman speaks of red splotches on the chest and of swollen and tender varicose veins at the knee. Bergh of Copenhagen has seen, from 1866 to 1887, 887 cases of vulvar herpes. Many said it occurred at every menstruation. It was not dependent on syphilis. In most of these cases it must be considered a menstrual exanthema, probably

depending on troubles of innervation.) 15. A large number speak emphatically about the eyes being very tired—"Cannot read at night." A number also report hyperosmia. 17. One reports coryza always present with menstruation. Another reports coryza nearly always present. 19. The change most frequently mentioned is the loss of the natural glossy appearance. One reports that the hair "looks dead."

It would be interesting to know whether the hair normally excretes toxic products at this time as it normally excretes arsenic. It was shown by Professor Brouardel in 1891 that arsenic is eliminated through the skin, hair, and nails, and is probably stored up there. Dr. J. Reid of Redhill recently stated<sup>3</sup> that in the case of patients taking small doses of arsenic, if the medulla of the hair after being treated by ammonia copper solution be viewed by a one-sixth of an inch objective, particles of arsenite of copper may be seen as small green granules. This matter of the excretion of arsenic by the hair has recently been discussed by Mr. Edmund Knecht, Ph.D., and Mr. W. F. Dearden, in connexion with the Manchester epidemic of arsenic poisoning by beer, and M. Gautier of Paris has shown that it is a normal function of the hair to eliminate arsenic from the system. In connexion with the elimination of arsenic at menstruation it must be mentioned that M. Gautier and M. Donser<sup>4</sup> have shown that menstrual blood contains four times as much iodine as normal blood, and that the total amount of arsenic eliminated in the menstrual blood at each menstruation is 0.14 milligramme, and this is equal to the entire quantity of arsenic normally contained in the thyroid gland. Iodine is also furnished by the thyroid gland.

Several interesting phenomena are suggested for observation by the replies received. In one pre-menstrual hunger is mentioned. Six report feeling cold, with shivering and chills, at the onset of menstruation, while swollen feet, stiffness of joints, and the assumption of a coarser appearance and texture by the skin are respectively mentioned by three correspondents. In one reply a hæmorrhage which occurs regularly within the external ear (concha) is reported. The first hæmorrhage is small and the blood soon coagulates, but if the coagulum be removed the hæmorrhage continues for some time, and though small is somewhat difficult to stop. This and the petechiæ upon the chest and shoulders are evidently connected. (Increased permeability of capillary walls?) Another correspondent reports a spot of hyperæsthesia over the right ear. This is interesting in connexion with the work of Dr. Fleiss of Berlin, who in 1897<sup>5</sup> stated that there were certain "nasal genital spots" which became swollen at the time of menstruation and which on being touched at this period (in rare cases at intermenstrual periods also) gave rise to pain. Touching the anterior end of the inferior turbinated bone gave rise to pain in the hypogastrio region, and touching the tuberculum septi gave rise to pain in the sacral region. Cocainisation of these spots relieves the pain of that type of dysmenorrhœa which does not cease with the flow of blood, and cauterising these spots completely will effect a cure of the same type of dysmenorrhœa. Dr. Fleiss's results have been completely confirmed during the last three years by Dr. Schiff of Vienna and other observers. It would seem that the mucous membranes are specially affected in menstruation. Thus the throat is frequently affected; the nasal mucous membrane is congested and swollen, and Goodman quotes two cases of hæmorrhage from the throat and upper part of the œsophagus. A similar case occurred in practice in Toronto recently.

Another interesting topic is the action and reaction of menstruation on disease and disease on menstruation—that is, the action of a physiological function on a pathological condition and *vice versa*. Typhoid fever precipitates menstruation, generally bringing it on within a few days after the onset of the fever. Other examples are as follows. Acne.—"Not infrequently patients give a history of their faces being worse at the menstrual period" (Dr. P. Abraham, surgeon to the Hospital for Diseases of the Skin, Blackfriars, and dermatologist to the West London Hospital<sup>6</sup>). Gonorrhœa.—"Examine suspected cases in female patients near the menstrual period, because a case in which the gonococcus is usually difficult to find will at this time show it in

<sup>3</sup> THE LANCET, March 23rd, 1901, p. 878.

<sup>4</sup> Académie de Médecine, 1900.

<sup>5</sup> The Relation of the Mucous Membrane of the Nose to the Sexual Organs in Females.

<sup>6</sup> THE LANCET, Sept. 22nd, 1900, p. 860.

great profusion" (Dr. W. H. Burrage).<sup>7</sup> Uterine myomata.—"About 10 to 14 days before menstruation a uterine myoma may frequently be found to increase in size, and a corresponding decrease occurs immediately after menstruation" (Dr. Thienhaus<sup>8</sup>). Tuberculosis.—"Not rarely it is possible in suspected persons in whom an examination previously had been negative to demonstrate positive signs during the menstrual period. In other patients the symptoms in the beginning of menstruation are not modified, but towards the end show a marked improvement" (Neumann). Effusion into the knee-joint.—Sir W. H. Bennett<sup>9</sup> reports 20 cases of a quiet, passive effusion into the knee-joint occurring in women and young girls which is always associated with menstrual irregularity or uterine trouble. In no case did recovery occur while the uterine or catamenial irregularities continued, but in every case their correction was followed by prompt improvement in the condition of the knee.

#### Temperature.

It is long since the question of variations of temperature more or less connected with the onset of menstruation first attracted attention. Longuet was of opinion that women have habitually a higher temperature than men. And though these variations are slight they are not always unimportant. Thus the accompanying observations show that in persons enjoying the most robust health a temperature of from 99° to 99.6° F. is not uncommon from 2 to 8 P.M. three or four days before menstruation, and in 13 out of 17 charts the afternoon temperature frequently reached 99° F. Yet a temperature of 99° F. is often looked on with suspicion. "Charts were here exhibited showing that in some cases a pre-menstrual rise of temperature might indicate early phthisis" (address delivered by Professor Clifford Allbutt before the British Medical Association at Portsmouth August, 1899<sup>10</sup>). "A rise of temperature to about 99° F. between 2 and 6 P.M. is one of the three earliest symptoms of tuberculosis" (address delivered by Dr. G. A. Heron before the Section of Sanitary Science and Preventive Medicine at the Congress at Southampton<sup>11</sup>). "Dr. Kingston Fowler has shown that the only form of pyrexia which can be absolutely said to be tuberculous is that in which the morning temperature is higher than that of the evening."<sup>12</sup>

In seeking information about normal temperature one turns to the classical work of Jürgensen<sup>13</sup> undertaken in 1866 and 1867. The measurements of temperature were taken from three healthy men, aged 24, 41, and 42 years respectively. Variations of 0.8° C. and even of 1.4° C. were found between the readings of the temperature of the same individual at different hours. Jürgensen was able to establish not only the average normal temperature of men in health, but also to show that even when there are "extreme conditions of life" the average temperature remains the same, if a long enough range be taken. Thus fasting and cold bathing, though they temporarily lower the body temperature, do not in the long run affect the average. Exercise too, often raises the body temperature, but not always, as Dr. W. Hale White has shown in the Croonian Lectures for 1897 on "The Means by which the Temperature of the Body is Maintained in Health and Disease." This fact was also noticed in some of the charts now dealt with. Another investigator who pursued the same subject was Georg Hormann.<sup>14</sup> Hormann finds the maximum temperature between 5 and 7 P.M. and the minimum between 5 and 6 A.M. His results are as follows: 1. Usual way of life, nourishment and exercise, 38.1° to 36.0° C. 2. Usual way of life, no food or drink for 36 hours, exercise, 36.5° to 36.0° C. 3. Usual way of life, hard work, nourishment, 38.1° to 36.3° C. 4. Usual way of life, nourishment, rest, 37.5° to 36.2° C. 5. Rest, nourishment withdrawn, 36.4° to 37.3° C. 6. Rest, nourishment withdrawn, constant outer temperature, 37.7° to 35.9° C. Sometimes the maximum temperature occurs at 2 or 3 P.M. and sometimes the temperature is low at 6 P.M. Something must depend on the dinner-hour and upon mental exertion, which sometimes, especially in warm countries,

produces a rise of temperature of from half a degree to one degree Fahrenheit (Fothergill and Murrell). There are also interesting records of race-variations of temperature. One of the most interesting of these occurs in the Goorkhas. Some years ago a writer in the *Indian Medical Gazette* drew attention to the fact that Goorkhas recovering from typhoid fever were not well until the temperature went down to 97° F., and added some further remarks on the "normal Goorkha temperature." Captain Lalor, I.M.S., has recently given an account in the same medical magazine of feeding with sugar six healthy men in a Goorkha regiment. For 11 days before administering sugar the temperature was 97.1° F.; for 11 days during its administration 97.4° were registered; and for 11 days after its administration, 97.2°. The temperature rose in every case while the men were being fed with sugar. Captain Lalor's theory is that the low temperature is due to defective metabolism.

References to temperature in connexion with the subject of menstruation are chiefly to be found in the literature of the so-called "Cyclical Theory of Menstruation," a term that seems to have been used first by the professor of obstetrics in Louisville Medical College, Dr. Goodman.<sup>15</sup> Dr. Goodman makes slight reference to variations in pulse and temperature. His theory is that menstruation is the result of a general condition of the vascular system due to the rhythmic action of nervous centres.

Dr. A. E. Giles's<sup>16</sup> observations were taken upon patients who were admitted to the Chelsea Hospital for Women for "trifling conditions" such as ruptured perineum, stenosis of the os externum, urethral caruncle, cervical erosion, &c. Many had no operation performed, and in the case of the remainder the observations were either made before operation or begun at least a week after operation. Even so they can hardly be considered women in robust health under normal conditions. A brief summary of Dr. Giles's paper is as follows: Temperature observations—50 menstrual periods in 45 patients. Conclusions.—That the temperature is lowest at the middle of the inter-menstrual period, gradually rises to a maximum two days before menstruation, falls suddenly on the day preceding the flow, falls again, but more slightly, at the end of the period, rises slightly for the first week thereafter, and finally falls slightly at the beginning of the inter-menstrual period (Fig. 1). Blood-pressure.—Seven patients, nine menstrual periods, 40 observations. Blood-pressure greatest on the first two days of menstruation and on the day preceding menstruation; it is lower during the remainder of the period, but rises again slightly after its cessation. Pulse tracings taken by Dudgeon's sphygmograph. The author does not entirely agree with the cyclical theory of menstruation, but regards menstruation as the "conclusion of the reproductive phase of an alteration of nutritive and reproductive activity," whereas the cyclical theory regards menstruation as the result of a periodical "variation of metabolic activity" or "nutrition wave" manifested by variations in the temperature, blood-pressure, and amount of urea excreted per diem.

The first record of observations made upon the temperature during menstruation appears to be by Fricke<sup>17</sup> in 1838. He states that the temperature is slightly higher during menstruation.

In 1867 Squire<sup>18</sup> observed that there was a rise in temperature before menstruation and a fall at the time when menstruation occurred.

In 1870, Rabuteau<sup>19</sup> recorded a series of observations which showed that the amount of CO<sub>2</sub> excreted during the menstrual period was considerably less than at other times; also that the amount of urea excreted was less just previously to menstruation, and that it rose again after menstruation. The same writer has recorded further observations on pulse and temperature.

A brief summary of the results recorded by more recent writers may be given. Daily excretion of urea.—Maximum, just before menstruation. Minimum, just after menstruation. Gradual increase from minimum to maximum. Temperature.—A slight rise for about seven days before menstruation is followed by a fall just before the onset. Another

rise of temperature is observed during the period. Blood-pressure.—This is below the average during the period, after the period it gradually rises, and there is a distinct decrease in blood-pressure either shortly before or at the time of the onset of menstruation.

Ott<sup>20</sup> of St. Petersburg, who gives a record of observations upon blood-pressure in 14 cases in which he used Basch's apparatus, finds that in 13 of these cases the blood-pressure fell considerably with the onset of menstruation, remained under the average during the period, and rose again after the flow ceased. The author concludes that the vasomotor system is the chief agent in preparation for reproductive activity and that this is proven by the variations of pulse and temperature, and by nervous symptoms as well as by changes in the uterus and ovaries.

A valuable contribution to the study of this subject was made in 1886 by the professor of materia medica in the Women's Medical College at New York City, Dr. Mary P. Jacobi.<sup>21</sup> In that year the Boylston Medical Committee appointed by the President and Fellows of Harvard University offered a prize of \$200 for the best essay on the following question: "Do Women require Mental and Bodily Rest during Menstruation, and to what extent?" The prize was awarded to Dr. Jacobi and her dissertation, a volume of more than 200 pages, thus became the Boylston Prize Essay of Harvard University for 1886. It is a careful and elaborate discussion of the subject. Dr. Jacobi collected many statistics and found, in the majority of cases, the following results. Excretion of urea.—Maximum a few days before menstruation and minimum immediately after; the amount decreases during menstruation. Pulse.—No uniform rate of variation. Temperature.—Rises just before menstruation, falls during menstruation. Arterial tension.—Maximum just before menstruation and minimum just after; rapid decrease during the menstrual flow.

The results of Dr. W. Stephenson,<sup>22</sup> professor of midwifery in the University of Aberdeen, are based upon four cases (the dates of all observations mentioned being June and July); a summary of his statement is here given in his own words:—

1. That menstrual life is associated with a well-marked wave of vital energy which manifests itself in the temperature of the body, in the

daily amount of the excretion of urea, and to a slighter extent in the pulse-rate. 2. That the cycle of changes takes a true wave-form divisible as to time into two nearly equal parts, the one below the other above the average for the whole period. 3. That the length of this wave varies in different individuals and may also vary in the same person. The urea wave and the temperature wave are equal in length in the same case. 4. That menstruation does not correspond with the apex or climax of the waves, but occurs five or six days after the decline has begun. It is probable that normally it occurs when the temperature curve reaches the mean; this was the case in nine out of 10 menstruations. The flow or evacuation cannot be regarded as the cause of the decline. 5. That the temperature wave is the most uniform and gradual in its rise and fall. In the urea curve the transition to elevation takes place more quickly, even suddenly. 6. That the temperature wave and the urea wave are independent of each other. 7. That whilst the pulse wave is not so marked in character it also shows a decided influence; it is depressed after menstruation and manifests a distinct rise some days before the next period. 8. In all the waves there are evidences of secondary waves.

The observations of Reinl<sup>23</sup> were based upon statistics obtained from 18 "relatively healthy" women, as far as possible alike in nourishment. The record includes 29 menstruations. These "relatively healthy" patients were suffering from chlorosis, version of the uterus, weakening of ligaments and walls of the vagina, &c. Only one was a virgin and their ages ranged from 24 to 41 years. Dr. Reinl finds a pre-menstrual rise of temperature, a menstrual fall, and a still lower post-menstrual temperature (Fig. 2).

The original single charts were arranged for recording observations every two hours for one week and then twice daily for four weeks. Fourteen two-hour charts and 20 records taken twice daily were received. It was specially requested that the same thermometer should always be used. Three of the 20 records being taken by nurses on night duty were not used in finding the average, but they presented the same features as the others. The chart shows a rise of temperature in the pre-menstrual period, a rise of temperature during the menstrual period, a fall of temperature just before menstruation, a fall of temperature at the end of menstruation, and a minimum temperature during the inter-menstrual period.

It remains to consider the large percentage of affirmative answers received to the questions. There is no doubt that the percentage, though large, is lower than it should be, for reasons already referred to. Several of those who kindly sent papers remarked afterwards that if they had the papers again they could put down more affirmative answers; when

their attention was drawn to the subject they observed what had previously passed unnoticed.

One can hardly consider the results of this inquiry without asking what these phenomena mean. If we could interpret them perhaps we should be more able to explain the true significance of menstruation. Nos. 1 to 9, and to a greater or less extent Nos. 14, 15, and 18, of the replies seem to originate from some condition of the nervous system. Nos.

10, 11, 12, and 19 seem to belong to metabolic processes. No. 13 may be explained by the high blood-pressure, and it may be that the increase of urea and the decrease of  $\text{CO}_2$  are connected. Nos. 20 and 21 are connected with the activity of the uterine glands and Nos. 16 and 17 would seem to indicate a lessened power of resistance, or a greater liability to infection. Toronto.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CASE OF LARGE PERI-NEPHRITIC ABSCESS WITH UNUSUAL SEQUEL.

By HENRY MALLINS, M.B., M.Ch. DUB.

A BOY, aged 14 years, was admitted into the Watton Cottage Hospital on July 22nd suffering from a painful swelling of the left side of the abdomen. On examination it was found that this region was dull on percussion from the ribs to the iliac crest, the line of dullness extending from the flank to within an inch of the median line. The lumbar region was distinctly bulged and was the seat of the chief pain. Pressure could be borne over the swelling in front. As he had been suffering from bladder trouble for several years the diagnosis of peri-nephritic abscess was made. The boy was so emaciated and the pulse was so feeble that any operative interference was deemed inadvisable. After a week's interval the swelling of the side commenced to disappear, as did also the dullness, and for a week before his death on August 16th all trace of it had gone. The emaciation was of the most marked description. At the post-mortem examination, which was made the next day, general peritonitis was observed. Distinct traces of a huge abscess extending from the stomach above to the sheath of the left psoas muscle below were found, the pelvis being full of large pieces of purulent lymph and the muscle sheath distended with thin yellow pus. The left kidney, enlarged to the size of that of a bullock, was practically converted into a bag of pus, which had evidently given way at a point on its convex surface, thus forming the starting point of the abscess, to which nature seems to have tried to put a limit by the formation of a wall of lymph, so poorly organised that it in the end gave way, permitting the contents to diffuse into the peritoneal cavity and thus explaining the disappearance of the swelling. The right kidney was also enlarged and was the seat of several deposits of caseous pus.

There was, unfortunately, no time to examine the bladder, as the examination, which was made under considerable difficulties, had to be abruptly terminated owing to the

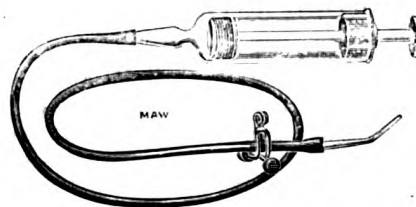

interference of a relative. As the mother had suffered from hip-joint disease since childhood I have but little doubt that a tuberculous ulcer of the bladder slowly infected the kidneys and led to the phenomena above recorded.

Watton, Norfolk.

#### SUBMAMMARY INJECTION OF SALINE SOLUTION IN THE TREATMENT OF COLLAPSE DURING AND AFTER POST-PARTUM HÆMORRHAGE.

By FRANCIS FOULDS, M.R.C.S. ENG., L.R.C.P. LOND.

In a recent case of collapse from post-partum hæmorrhage I injected 25 ounces of warm saline solution into the sub-mammary cellular tissue by means of the simple apparatus (of which an illustration is here given) brought to my notice by Dr. Drummond Robinson and made by Messrs. Maw, Son, and Thompson. Before the injection the patient

was almost pulseless (having no radial pulse) and was ghastly pale. She had sighing respirations, with a large, flabby, uncontracted uterus from which the placenta had to be peeled, and the hæmorrhage could only be controlled by bimanual compression. Within five minutes of the introduction of the saline fluid the pulse could be discerned at the wrist. The facial appearance and the character of the respirations improved and the patient regained consciousness—although her condition remained critical for several hours. She made a slow but uneventful recovery and is now in good health. In his "Handbook of Midwifery," Dr. Dakin states that "Münchmeyer injected saline fluid into the connective tissue and muscles of the back, &c.," and then goes on to say that the process is slow, and if the woman is in a dangerous state, too slow to be of any use. In this case the whole of the fluid was absorbed in

three-quarters of an hour but the improvement in the patient's condition was almost immediate, and I think this was because the site of the injection was near to the heart.

At any rate this method will appeal to the general practitioner as being far more expeditious than, and preferable to, hunting for the median basilic vein in a dying woman, and more trustworthy than rectal injection of saline fluid with its almost inevitable expulsion.

A little tenderness of the breast remained for a day or two and the secretion of milk was disturbed, but this latter is a negligible quantity, as one would naturally not allow the patient to suckle the child under the circumstances.

Droitwich.

#### PTOSIS OF THE LIVER.

BY COURTNEY NEDWILL, M.D. R.U.I., M.R.C.S. ENG.,  
VISITING SURGEON TO CHRISTCHURCH HOSPITAL, NEW ZEALAND.

MR. TREVES, in THE LANCET of May 12th, 1900, p. 1239, states that there are 80 recorded cases of ptosis of the liver, and says that out of this number only one is reported with hydatid cyst.

In July of last year an anæmic unmarried female, aged 27 years, came under my care at the Christchurch Hospital complaining a good deal of dragging pain in the side and back, more especially on standing. A large smooth and moveable tumour occupied the right side, descending towards the crest of the ilium. It could be pushed easily about from side to side and upwards and downwards. The costal level of liver dulness upwards was lower than normal. Opinions varied as to the nature of the tumour. On opening the abdomen the liver substance appeared to be normal, but situated in the lower anterior border there was a hydatid cyst close to the surface and not bigger than a turkey's egg. This was evacuated and the lining membrane was cleared out, wiped dry, and returned into the abdomen. Nothing was done in any way for the ptosis. Since her discharge from the hospital the patient has reported herself as being quite well.

Christchurch, New Zealand.

#### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

#### BRADFORD ROYAL INFIRMARY.

A CASE OF ANGIOMA OF THE MAMMA.

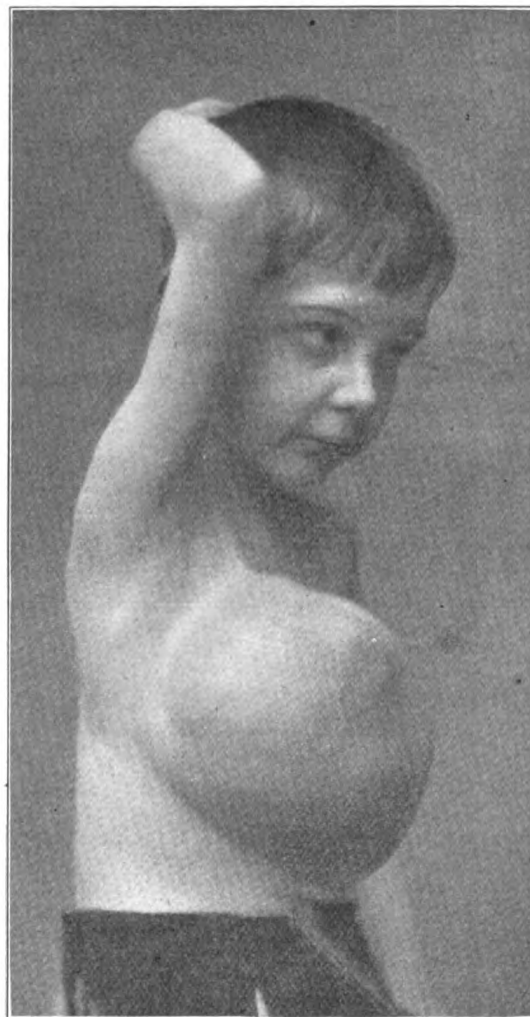

(Under the care of Dr. C. F. M. ALTHORP.)

ANGIOMA is one of the rarer new growths of the breast and may occur both in men and in women. The number of cases recorded up to the present is very small and therefore the following case well deserves to be recorded. Another case in a male subject has been published by Mr. J. Bland-Sutton.<sup>1</sup>

On Jan. 12th, 1901, a boy, aged seven years, was admitted into the Bradford Royal Infirmary under the care of Dr. C. F. M. Althorp, on account of an enormous tumour in the region of the right breast. When the patient was born a small swelling of the size of a hen's egg was noticed near the nipple of the right breast. So far as the parents could remember the skin was not discoloured. As the boy grew the tumour slowly increased in size, but it did not inconvenience him in any way nor did it prevent him from playing football and other games. Whilst at play on Dec. 29th, 1900, he received a severe knock on the tumour, in consequence of which it was noticed that there was a sudden

increase in the size of the tumour, with discolouration of the skin. From day to day the swelling rapidly increased in size, so that in 14 days it became twice the size it was before.

FIG. 1.

Condition before operation.

the accident. Fig. 1 shows the condition of the boy on admission. The skin over the tumour was discoloured in places and the superficial veins were enlarged. The swelling as a whole was freely moveable over the front of the chest-wall, its surface was lobulated, and in places there was evidence of fluctuation. In other respects the boy was in good health.

On Jan. 16th ether was given and the tumour was removed. A curved incision was made along the upper margin of the growth and the flap of skin was dissected upwards. The wound was deepened until the pectoralis major muscle was reached, and part of the muscle was removed with the growth. In this way the tumour was undermined and separated from the chest-wall. There was free bleeding. A second flap was raised along the lower border and a third flap from the upper and outer borders of the growth. In a few places small cysts were opened and much liquid, dark-coloured blood escaped. The tumour was in this way rapidly enucleated. Bleeding points having been tied the wound was closed with silkworm-gut sutures, no drain being used. A dressing of gauze and wool was kept on by a bandage. The operation lasted for half an hour and the patient stood it very well. Before the ether was given he had strychnine injected hypodermically and a rectal injection of brandy.

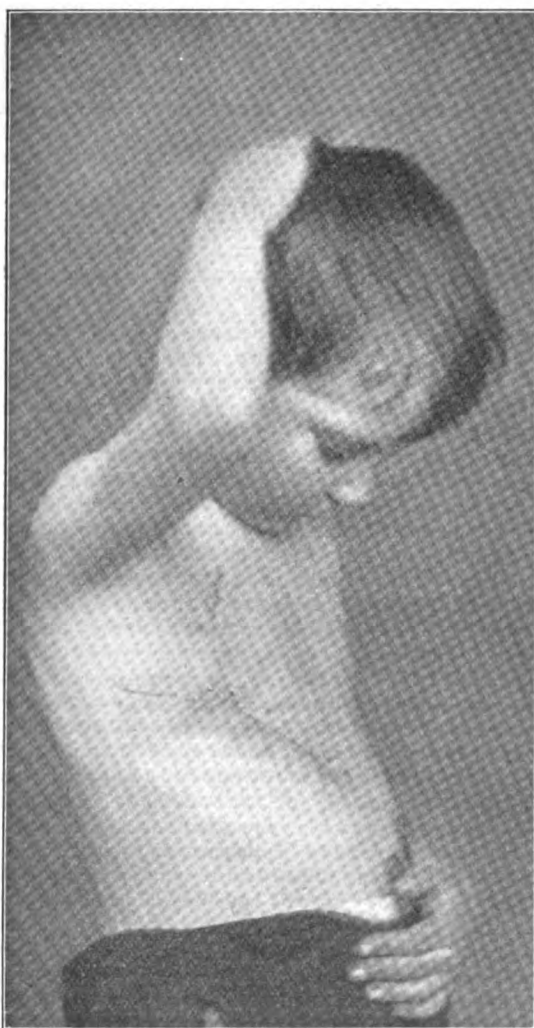

<sup>1</sup> Transactions of the Clinical Society of London, vol. xxii., p. 187.

The after-history was uneventful. On the sixth day after the operation the wound was dressed; it was found to be dry and half of the stitches were removed. The patient got up on the eighth day and the remainder of the stitches were removed on the thirteenth day. Since then the boy has been seen from time to time and in September was in robust health and locally the wound was soundly healed and presented the appearance shown in Fig. 2.

*Remarks by Dr. ALTHORP.*—After the operation the growth was cut into and 30 ounces of dark-coloured liquid blood came away, the tumour collapsing as the blood ran out. This was on account of the tumour being formed of small cysts which did not communicate with one another. Dr. F. W. Eurich kindly examined the tissue microscopically and found (1) much unstriated muscle, (2) cavernous tissue, and (3) myxomatous tissue. This appeared to point to the tumour being similar to those described by Virchow as "myomata of the unstriated muscular tissue of the areola and nipple, with telangiectasis." Before removal the tumour measured  $21\frac{1}{2}$  inches in circumference,  $11\frac{1}{2}$  inches from above downwards, and  $14\frac{1}{2}$  inches from side to side.

The case is worthy of being recorded on account of its extreme rarity. Very few references to the subject of angioma of the breast are to be found in surgical text-books.

FIG. 2.

Condition after operation.

Mr. Marmaduke Sheild in his work on "Diseases of the Breast" states that "true cavernous tumour implicating the breast substance is very exceptional," and that he has "never met with a case where the skin was not principally

affected." He also gives details of a case, which is mentioned as "the most remarkable case ever related in this country of angioma of the mamma" (which is reported in detail in Vol. XXX. of the Transactions of the Royal Medical and Chirurgical Society). It was in 1845, and Mr. Image of Bury St. Edmunds had charge of the patient, a girl, aged 21 years. The left breast measured 15 inches in circumference and 11 inches horizontally. Removal was attempted by strangulating the vessels at the base by ligatures, having turned back two flaps on either side. There was so much loss of blood that the patient died the same night.

No allusion to the subject of angioma of the breast is to be found in the works of Velpeau and of Gross. Langenbech mentions a case where the arteries and veins were so dilated that the mass resembled a vascular goitre. Even in two of the most recent surgical works the subject is only referred to as "occurring so rarely that no further reference need be made,"<sup>1</sup> and "angioma of the mammary gland is occasionally seen."<sup>2</sup>

## MIDDLE WARD HOSPITAL, MOTHERWELL.

### A CASE OF DRY GANGRENE IN SCARLET FEVER.

(Under the care of Dr. JOHN J. BUCHAN.)

GANGRENE as a rare complication of scarlet fever is of great interest, especially from the point of view of its etiology. The gangrene is usually bilateral and symmetrical and this fact in itself demonstrates conclusively that at all events in most cases it cannot be embolic in origin; this is also shown by the fact that it is nearly always "dry," for embolic gangrene is almost invariably of the moist variety. Dry gangrene can only occur when the blood-supply to a part is slowly diminished so that the veins and lymphatics can carry off the fluids of the limb. From these considerations we may conclude that the lumen of the vessel is gradually narrowed, probably by clotting, and that this thrombosis is assisted by the condition of the blood.

A boy, aged 13 years, was, on March 23rd, 1900, admitted to the Middle Ward Hospital, Motherwell, notified to be suffering from scarlet fever. His history previously to admission was as follows. His present illness commenced on March 20th with sore-throat, sickness, and vomiting. On the 22nd the scarlatinal rash appeared on the chest and spread over the trunk and limbs. No definite history of recent injury was obtained. On admission a brilliant typical rash was seen on the trunk and limbs; in colour the rash was bright scarlet on the trunk, but it had rather a bluish appearance on the limbs. The hands and feet were blue and cold. The tonsils, the pillars of the fauces, and the soft palate were swollen and reddened, but the inflammatory state of the throat was not great. The pulse was exceedingly rapid, numbering 150 to the minute; it was not easily felt and tended to be irregular. The temperature was  $104.2^{\circ}\text{F}$ . There was, however, no delirium. The special treatment resorted to was cold sponging every four hours to bring down the temperature and the administration of one drachm of whisky every two hours.

On March 24th the temperature was  $102^{\circ}$  in the morning and  $102.6^{\circ}$  in the evening. The urine contained a considerable amount of albumin. The pulse was 150 to the minute and irregular. The hands and feet were still blue and cold. The whisky was increased to two drachms every two hours and a mixture containing tincture of digitalis and liquor strychninæ in one and a half minim doses of each was given every four hours. Ten cubic centimetres of anti-streptococcic serum (Burroughs, Wellcome, and Co.) were injected. On the 25th the temperature was  $100.2^{\circ}$  in the morning and  $100.4^{\circ}$  in the evening. Both legs showed blue engorged veins standing out from the still brilliant rash; this was best seen in the right leg, in which about the apex of Scarpa's triangle and in the back of the calf pain was felt. On the 26th the temperature was  $99^{\circ}$  in the morning and  $99.6^{\circ}$  in the evening. The stimulant was stopped, but the digitalis and strychnine mixture was continued. The heart was normal to examination. On the 27th the temperature was  $100.4^{\circ}$  in the morning and  $100.6^{\circ}$  in the evening. The patient had a slight epistaxis in the morning and the urine for the first time contained blood. The left leg was much better, but the

<sup>1</sup> Mr. H. J. Stiles in his article on Diseases of the Breast, *Encyclopædia Medica*, vol. vii.

<sup>2</sup> Dr. Warren: *International Text-book of Surgery*—Gould and Warren.

right leg was worse. Pain was still felt at the apex of Scarpa's triangle and right down in a line to the back of the calf. A hæmorrhage took place underneath the skin on the inside of the calf, forming a large bluish blotch. On the 28th the temperature was 100·6° in the morning and 102·2° in the evening. The heart was still normal to examination and the urine still contained albumin and blood. The sputum on this day was blood-tinged but there were no abnormal physical signs in the lungs. No pain was complained of anywhere except in the right leg, where it continued in all its severity. The hæmorrhagic blotch of the 27th had spread particularly downwards and was joined by other smaller blotches. Always cold and blue, the right leg was noted on this day to be almost dead cold. On the 29th there was no improvement at all. A hæmorrhagic spot appeared over the patella, there was slight epistaxis, and the urine still contained albumin and blood in considerable amount. On the 31st a line of redness was noted as appearing across the leg and running obliquely downwards and backwards from just above the patella. This seemed to indicate the beginning of a line of demarcation; below this the leg was becoming distinctly gangrenous. On April 3rd the temperature settled to normal. The urine contained no blood but was still albuminous. From this date there was no further epistaxis or hæmoptysis and albumin entirely disappeared from the urine on May 2nd. The lower part of the right leg became mummified and a definite line of demarcation formed just above the knee. Professor D. N. Knox of the Glasgow Royal Infirmary, after seeing the case several times, decided to amputate the leg, which he did on May 5th. The boy made a rapid and complete recovery.

*Remarks by Dr. BUCHAN.*—The special points of interest to be noted about this clinical history are as follows. The patient was a boy, 13 years of age, suffering from scarlet fever of a most severe type, presenting many of the so-called "malignant" characters; the disease was at different times complicated by hæmaturia, epistaxis, and hæmoptysis. The first symptoms of gangrene appeared on the sixth day of scarlet fever as blue engorged veins and pain in the leg and on the eighth day of the disease a subcutaneous hæmorrhage took place. The extent of the gangrene was manifest by the twelfth day of the disease, although the line of demarcation was not distinct until some time after this.

Considering the great frequency of scarlet fever and the large number of carefully recorded observations made this complication of the disease must be excessively rare. Hochenegg,<sup>1</sup> Osler,<sup>2</sup> and others mention symmetrical gangrene as arising in scarlet fever, while the former in doing so points out that symmetry is not always characteristic of gangrene in scarlet fever. Holmes<sup>3</sup> records a case of gangrene of the left leg in this disease in the case of a woman, aged 40 years, while Pearson and Littlewood<sup>4</sup> have put on record an exceedingly interesting case of dry gangrene in scarlet fever affecting both legs on the ninth day of the disease in a boy, four years of age, and necessitating amputation.

But though in scarlet fever dry gangrene so seldom occurs in several of the other specific fevers, notably typhus fever and typhoid fever, gangrene has been long a well-recognised complication.<sup>5</sup> In these fevers its occurrence does not altogether depend on the duration of the disease, as Moore<sup>6</sup> has recorded the case of a patient with typhus fever dying on the fourth day of the disease from gangrene of the fingers. Undoubtedly, however, the lengthened duration of the pyrexia in these latter diseases exercises a great influence on its more frequent occurrence in them. At the same time cognisance must be taken of the fact that though the duration of the pyrexia in scarlet fever is usually much shorter yet the intensity of the action of the virus is in a large number of cases—as in the above case—much greater than in typhoid fever or typhus fever, and, further, that in scarlet fever we occasionally meet with a typhoid form in which the duration is greatly lengthened.<sup>7</sup>

In regarding the circumstances favourable to the production of gangrene in scarlet fever we may consider three groups—(1) the change in the blood, (2) the weakened heart, and (3) the mechanical difficulties of the circulation.

The blood in scarlet fever becomes greatly impoverished through the mere maintenance of the temperature of the body at a higher level<sup>8</sup> as well as through the growth of the organism causing the disease, while at this time the resources of the blood are not easily replenished nor are the accumulating waste products easily got rid of. At the same time the toxins generated by the virus are causing the blood to have a deleterious effect on the tissues. This is, of course, altogether apart from any local effect which the virus may have.

Though so good an authority as Osler<sup>9</sup> apparently regards myocardial changes as uncommon, yet Henschel,<sup>10</sup> Stengel,<sup>11</sup> and Mitchell Bruce<sup>12</sup> all lay stress on the frequent and marked changes found in the myocardium in this disease. Moore<sup>13</sup> states that "the heart muscle suffers severely, especially from the hyperpyrexia which accompanies the severer forms of the disease." In a case of malignant scarlet fever so early as the fourth day I have been able to make out on post-mortem examination the soft and distinctly friable character of the heart muscle. Indeed, it is almost impossible to think otherwise from the uniformly great frequency of the pulse in this disease and the clinical evidences of cardiac failure so often found. It is of some interest to note that Stengel<sup>14</sup> states that this acute diffuse myocarditis is more frequent in scarlet fever than in typhoid fever, though first noted in the latter disease. There can be little doubt that such a cardiac change influenced profoundly the occurrence of gangrene in the above case. The possibility of a detached valvular vegetation the result of scarlatinal endocarditis causing gangrene should not be lost sight of.

The mechanical difficulties of the circulation in certain parts of the body, such as the toes, ears, causing these parts to become gangrenous, are too well known to require comment.

## Reviews and Notices of Books.

*A Manual of Medicine.* Edited by W. H. ALLCHIN, M.D., F.R.C.P. Lond., F.R.S. Edin., Senior Physician and Lecturer on Clinical Medicine, Westminster Hospital. Vol. III., Diseases of the Nervous System. London: Macmillan and Co., Limited. 1901. Pp. 428. Price 7s. 6d.

THE third volume of Dr. Allchin's *Manual of Medicine* is a valuable and instructive text-book on diseases of the nervous system. Within recent years the anatomy and physiology of the nervous system have been thoroughly investigated and great advances have been made. A new terminology has been established, so that anyone not fully conversant with the terms recently introduced in this branch of medical science would be greatly at a loss to understand the theoretical discussions which must naturally arise in considering more especially the pathology of the diseases of the nervous system.

The editor has very wisely introduced an excellent article on the general anatomy and physiology of this system written by Professor C. S. Sherrington. This is a most valuable contribution and a careful study of it will enable the reader to understand the intricate structure of the nervous system and the manner of its working. The language employed, though somewhat terse, is exact and easily comprehended. The structure of the neuron is first described and then attention is directed to the root cells and reflex action. The bulbo-spinal axis with the afferent and efferent channels concerned therewith are fully described. The subject is a difficult one, but Professor Sherrington shows in this article a power of description which renders a comprehension of the complex problems involved as simple as such matters

can be made. The cell system of the spinal cord is rendered more easy of explanation by several diagrams, the numerous tracts being indicated by coloured patches. For the sake of clearness it would be better for physiologists to decide upon some terminology founded on an anatomical basis than to continue to use such terms as "Clarke's column," "Deiters' nucleus," &c. The author has apparently adopted this plan as far as possible, but numerous tracts and cells are still named after the observer who first described them.

As an introduction to "Diseases of the Nervous System" Dr. W. Aldren Turner has written an article under the heading: "The Neuron in its Relation to Disease of the Nervous System." In a modern text-book upon diseases of the central nervous system the separation of the affections above and below the level of the foramen magnum into cerebral and spinal disorders respectively no longer holds good. Dr. Turner points out that the present accepted conception of the constitution of the central nervous system is that of a series of neurons, some of which commence in the cerebrum and terminate in the spinal cord, while others, arising in the spinal cord and posterior spinal ganglia, terminate in the several portions of the brain. As many forms of organic nerve disease are at present construed as degenerations of one or other system of neurons it is clear that no hard-and-fast line can be drawn between disorders of cerebral origin and those of spinal origin. The classification of diseases of the central nervous system is now undergoing entire rearrangement and Dr. Turner gives a table of degenerations classified according to the neuron system primarily involved. Under this plan there are three main divisions: (1) the cerebro-spinal or upper efferent neuron system, commonly called the pyramidal system; (2) the spino-peripheral or lower efferent neuron system; and (3) the lowest afferent or posterior ganglion neuron system. There may be simultaneous affections of both the efferent neuron systems, as is the case in amyotrophic lateral sclerosis, and, finally, a few diseases would appear simultaneously to implicate the lowest afferent and the upper efferent neuron systems; Friedreich's ataxia is an example. Dr. Turner also contributes good articles on the Diseases of the Cerebral Membranes, Cerebral Vascular Lesions, Intracranial Syphilis, General Paralysis of the Insane, and Tumours of the Brain. He also writes on Focal Diagnosis.

The difficult subject of Aphasia and other Defects of Speech is ably considered by Dr. J. S. Collier. The question of an "ideational centre" is discussed. Dr. Charlton Bastian opposes the theory that there is such a centre, and Dr. Collier maintains that there is no pathological or clinical evidence of its existence.

Dr. J. A. Ormerod writes on Diseases of the Spinal Cord and its Membranes. He commences by referring to the fact, to which we have already drawn attention, that no actual division is anatomically possible between cerebral and spinal disease; convenience in treating the subject alone justifies any attempt at separation. The general morbid anatomy of the cord is well described and illustrated by some capital diagrams. The more modern methods of staining microscopical sections of the central nervous system have rendered the production of illustrations far more easy and satisfactory than was formerly the case, and those here shown (drawn from original preparations in the possession of Dr. W. A. Turner) demonstrate excellently the sclerosed areas he found in various diseases. The description of the affections of the spinal cord is all that could be desired and we can strongly recommend a study of these pages to students about to present themselves for examination. A useful "Table of Spinal Localisation" concludes this section of the volume.

The Muscular Dystrophies are also considered by Dr. J. A. Ormerod. The rare conditions, myotonia congenita and myasthenia gravis, are both described. Dr. Purves Stewart's

contribution on Diseases of the Peripheral Nervous System is likewise worthy of high praise. It is essentially practical throughout and the student will find therein, not only all the information he requires for his examinations, but also hints as to diagnosis and treatment which will be useful to him throughout his professional career. Dr. Stewart also writes on Lesions of the Cauda Equina and on Acute Ascending Paralysis. In his description of multiple neuritis Dr. Stewart has scarcely brought his observations up to date. He says, "Alcoholic neuritis is commoner than all the other varieties put together." He subsequently refers to the Manchester outbreak of neuritis, but does not discuss the doubts which have been thrown on the relative powers of alcohol and arsenic as etiological factors in the production of neuritis.

Dr. W. S. Colman and Dr. J. S. Collier are jointly responsible for a very interesting series of articles on Functional Diseases of the Nervous System. Amongst the most important of these is Epilepsy. We note that the term "cortical fits" is employed for the variety usually known as "Jacksonian"; this is in accord with the feeling we have already expressed that it is preferable not to call a disease after the observer who first described it, although due honour should be accorded to the physician or surgeon. The diagnosis between functional and organic disease frequently presents very great difficulties, but in the section on Hysteria the several points to be relied on when such a problem presents itself are clearly indicated. The editor contributes interesting articles on Headache and Trophic neuroses, whilst Dr. James Taylor writes on Medical Ophthalmology and Dr. Bertram Abrahams on the Medical Application of Electricity.

We can strongly recommend this volume to the notice of students. From their point of view it is one of the best, if not the best, of the manuals of diseases of the nervous system which we have seen. Practitioners also will find it most convenient for reference. Controversial points are not so fully discussed as in the larger text-books, but stress is laid on the practical points of the symptoms, diagnosis, and treatment.

*Topographie des Weiblichen Ureters. (Topography of the Ureters in the Female.)* By Dr. JULIUS TANDLER and Dr. JOSEF HALBAN. Atlas with 32 Chromo-lithographic Plates and Explanatory Text. Vienna: Wilhelm Braumüller. 1901. Price 30 marks.

THE importance of the anatomical relations of the ureters to the gynaecologist and obstetrician can hardly be overestimated. Their relations to the broad ligaments and cellular tissue of the pelvis play a great part in determining the difficulties and dangers of many of the operations performed upon the uterus, both by the vagina and by the abdomen. A clear and accurate knowledge of these ducts is therefore essential to all who practise operative gynaecology. This knowledge is best obtained by actual dissections of the pelvis. This is, however, a method of study not often available to the surgeon, and he is therefore compelled to fall back upon text-books and atlases of anatomy. The present atlas is a work of considerable value, and a study of its plates will do much towards familiarising the surgeon with the relations of the ureters both in the normal and also in many abnormal conditions of the pelvic organs. The book consists of 32 chromo-lithographic plates with explanatory letterpress. After a number of plates illustrating the normal anatomy of the ureters, and the dissections necessary to expose them through the abdominal wall with and without division of the peritoneum, a very important series of illustrations is given explaining the operation of total abdominal extirpation of the uterus. One of the arguments used by those in favour of supra-vaginal amputation of the uterus rather than total hysterectomy is the great

risk run by the ureters in the latter operation. The six plates illustrating the operation are therefore amongst the most important in the atlas, and show very clearly both the risks the ureters run and how best they may be avoided. The changes produced in the position of the ureters by drawing down the uterus are clearly shown, and the fact that in the operation of vaginal hysterectomy when properly performed the ureters are in very little danger can be clearly seen from the dissections. Plate XIX. is a most interesting one of a ureteral fistula following total extirpation of the uterus, due to the right ureter having been ligatured at too great a distance from the uterus. Plates XXI. and XXII. are valuable as showing the relations of the ureters after drawing aside the rectum in the sacral operation for removal of the uterus. Two sagittal sections are given showing the pregnant uterus at full term and its relation to the ureters. The anatomy of the uterus and bladder in a case of inversion of the puerperal uterus is figured in Plate XXV., and the normal relationship of these structures to the uninverted cervix is well seen. The elongation and dragging upon the ureters in cases of cystoceles is important and the plate illustrating a uretero-vaginal fistula in a case of carcinoma uteri shows how readily in this disease these ducts may be involved by the growth extending beyond the cervix. The authors have been able to figure a very interesting case of double ureter in which the supplementary one is dilated and ends blindly in the anterior vaginal wall just within the vulvar orifice, as often happens in such cases. The whole work is one of great value and interest and both the authors and artist are to be congratulated upon the excellence of the dissections and the clearness and merit of the drawings illustrating them.

*Cyclopædia of the Diseases of Children.* Vol. V. Edited by WILLIAM A. EDWARDS, M.D. Illustrated. London: J. B. Lippincott Company. 1901. Pp. 1330. Price 25s.

THE Cyclopædia in its original form of four volumes was published in the year 1889 under the joint editorship of the late Dr. Keating and Dr. W. A. Edwards. Since then it has constituted the standard work on pediatrics, not only in those countries in which English is the national language, but in far countries, like Japan, where the English language is read. The rapid evolution of this comparatively new branch of medicine in many respects would have justified a completely new and revised edition, but no doubt the publishers and the present editor, Dr. Edwards, in adjudicating between the respective advantages of a new edition and a supplemental volume, have chosen the wiser course in adopting the latter alternative. The present volume, which is No. 5 of the series, includes with but few exceptions new or revised articles on every branch of pediatrics in which there has been any notable advance in the departments of pathology, etiology, or therapeutics. The entirely new matter comprises chapters on Auto-intoxication, by Dr. J. J. Putnam and Dr. E. W. Taylor; on Toxins and Antitoxins, by Dr. Victor C. Vaughan; on the Normal Præcordia of Infancy and Childhood, by Dr. A. R. Edwards; on Fibroid Disease of the Lung, by Dr. F. A. Packard; on Infantile Atrophy, by Dr. John Lovett Morse; on the Roentgen Rays in the Surgery of Children, by Dr. W. W. Keen; and on Epiphyseal Separations, by Dr. R. H. Harte. Some few of the revised articles appear under the names of authors who wrote for the Cyclopædia in its original form, and this is notably the case in the articles on Rheumatism, Infantile Scurvy, Functional Diseases of the Heart, and the Feeding in Infancy and Early Childhood which emanate respectively from the pens of Dr. Cheadle, Sir Thomas Barlow, Dr. J. M. Da Costa, and Dr. H. Rotch. As regards the majority of revised articles there appears to have been, if we may use

the expression, a sort of "general post" among the contributors. The same names appear but over different chapters. We notice, however, with regret that Dr. Holt, who originally was responsible for the article on Diarrhoeal Disease, has not in the supplemental volume given the Cyclopædia the benefit of his writing. This is no doubt due to the fact that he himself is engaged in revising his own excellent work on the Diseases of Childhood. We notice, further, certain alterations in the nomenclature of disease—for instance, what was originally called "membranous enteritis" is now entitled "mucous disease," the name, we believe, given to the condition by Dr. Eustace Smith. The article on this subject is contributed by Dr. L. Starr. Inflammatory disease in the neighbourhood of the cæcum is now included under the title of "appendicitis"; originally it bore the somewhat cumbrous titles of "perityphlitis," "paratyphlitis," and "perityphlitic abscess."

As regards the subject-matter in the more important additions in the supplemental volume we notice that in the article on Auto-intoxication Albu's classification is accepted. In this classification are included a large number of diseases which in the earlier volumes were distinctly regarded as of extrinsic origin, and in this respect the evolution of the pathogenesis of tetany is particularly interesting; originally it was included among the diseases of the peripheral nervous system. In the present volume Dr. E. W. Taylor claims it as belonging to his series of auto-intoxications, and Dr. F. X. Dercum writes a special article on the subject, in which he unreservedly declares for the thymic origin. To quote his own words: "All the facts in regard to tetany can be reconciled by supposing that tetany occurs by reason of some impairment of the function of the thymus gland, and that the latter is no longer able to protect the organism against tetany-producing toxin. It does no violence to the facts to further suppose that the impairment of function is directly related to insufficient and improper food and bad hygiene."

It is impossible within the compass of a short review to do justice to the many additions to the Cyclopædia; from want of space we can do no more than refer to those which bring the important diseases of the nervous system into line with the almost revolutionary advances of modern neurology. In this connexion we would mention the articles on Amaurotic Family Idiocy, by Dr. B. Sachs, and that on Hereditary and Locomotor Ataxy, by Dr. Joseph Collins. It is, perhaps, to be regretted that the editor has not seen his way to include a revised article on rickets, the most common and perhaps indirectly the most serious complaint of childhood; and, further, as a work of reference many readers would have doubtless preferred to have seen perpetuated in the supplemental volume that excellent precedent (which was of special value in the first four volumes), of supplying a bibliography at the end of the most important articles. Dr. W. A. Edwards, however, deserves full credit for having in his single-handed capacity of editor of this supplemental volume fully maintained the traditions of the first four volumes.

ERRATUM.—In our review of Dr. Woods Hutchinson's "Studies in Human and Comparative Pathology," which appeared in THE LANCET of July 13th, 1901, p. 86, the name of Dr. Edward Blake, the Editor of the work, was erroneously printed as "Dr. Edward Lake."

DEVON COUNTY ASYLUM.—The Local Government Board inspector (Major Norton) held an inquiry at Exminster on Sept. 25th concerning the application of the St. Thomas Rural District Council for sanction to borrow £4110 for works of sewerage for Exminster. The application had arisen through the district council being under the necessity of finding means of disposing of the sewage of the Devon County Lunatic Asylum.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 5, 1901.

## The Reconstitution of the Royal Army Medical Corps.

It was with much gratification that we were enabled last week to refer by way of anticipation to some very noticeable points which we had good authority for stating would be found in the then forthcoming report of Mr. BRODRICK'S Committee on the Reorganisation of the Army Medical Services. Without liberty to use the complete text of the report we should not have been justified in saying more than we did, and it would, of course, have been altogether premature to have pronounced any definite opinion in regard to it. Still, the quality of the information was such as to be indicative of the spirit and aim with which the inquiry had been conducted and was very significant, at the same time, of the principles on which the new and complete scheme of army medical reform would be found to have been moulded. The report of the Committee appointed by the Secretary of State for War has now been published and the full text of it appears in the present number of THE LANCET. It need scarcely be said that it is a far-reaching document of great importance to our readers and well worthy of being carefully considered, and that not from any narrow or merely expert point of view. Its recommendations are of national interest and vitally concern our army as a whole—indirectly all armies, we might say. And their influence will not be circumscribed within the limits of the Army Medical Services, or be felt by the medical profession of this country alone, so that we would beg all our readers to approach the consideration of the report in a broad, comprehensive spirit—not looking to see how this or that grievance has been met, but placing themselves in the position of the Committee and trying to realise the all-round and sterling nature of the attempt to reorganise a most valuable branch of our national defences.

The report is a long and necessarily in parts a technical one; it has been drawn up apparently with great care and ingenuity, and evidently after full deliberation, for it traverses and covers most of, or all, the points which have been at different times the basis of dispute or difficulty. It is consequently very elaborate—indeed, many people may think it too elaborate. Such is not our impression. It seems to us that the inquiry has been set about with an earnest aim and conducted on sound principles, and the result is a report framed on bold and generous lines which warrants us in indulging in the hope and belief that a new and promising future is in store for the Royal Army Medical Corps. The effect and working of some of the recommendations must for the time perhaps partake more or less of the

nature of experiment. Others may have to be still further developed or may be modified. For example, it would be advisable that the Director-General should have a place on the Army Board that he might speak in support of the proposals of his Advisory Board. Time and experience will probably suggest other improvements. It may be regarded as an indication of the great importance which the Government attached to this inquiry that the Secretary of State for War in announcing the names of the Committee added that he proposed to take the chair himself. One distinct advantage of his having done so is that the recommendations will, no doubt, be carried out. It was quite clear from the constitution of the Committee, especially from the names and qualifications of the members of the medical profession in civil life who were appointed to serve on it, that the Government wanted to make of the Royal Army Medical Corps a division of the medical profession worth the while of the best student to enter; they wished to put the service on a permanently good footing and to keep it there. One of the great aims of the Committee has been to bring the Army Medical Services into the closest relations with the profession in civil life, and from start to finish of the report it may be seen that to this aim practical effect has been given.

Of course, the officers of the Royal Army Medical Corps have many other duties to discharge besides those of a purely medical character. Bearing this in mind the reader of the report of Mr. BRODRICK'S Committee may, perhaps, think that the medical path is too much strewn with examinations, and that *chevaux de frise* of conditions and examinations have been placed round every step of the army medical officer's career. We confess to a feeling of sympathy with this view, but it will be seen that the subjects of examination are to be as a rule of a really practical and clinical character. It was unavoidable that the Government should exact some test, if the principle of selection is to be followed, for the separation and reward of those who are specially entitled to consideration from those who are not. It has been said that money measures men; and the rates of pay are increased, provision is made in the way of bonuses for those who do not desire continuous army service, and an earnest attempt has been made to remedy the main grievances which have rendered the service unpopular. Under the system now to be inaugurated young men of high professional qualifications can enter the army for a time and relinquish the service without unduly sacrificing their subsequent chances in civil life: on the other hand, those who desire to make the service a permanent career will know that scope will be given for superior ability and professional attainments. It can no longer be said that under the new *régime* no encouragement is held out to men of professional skill and scientific attainments, or that the prosecution of medical and scientific research is ignored. We hope and believe that the medical profession will view the recommendations of Mr. BRODRICK'S Committee as we do and that they will consider that the terms offered to the Royal Army Medical Corps are liberal and such as open up a fine field to the young practitioner for the display of professional zeal and ability, together with the other qualities that characterise the manly man.

## The Introductory Addresses.

THE Introductory Addresses which we publish to-day present much variety of subject and will appeal to students—not to say practitioners—of different tastes and mental constitution. We make no attempt, of course, to discuss all the topics raised, and if we single the words of one or two of the speakers out for notice it is that we may deal more particularly with questions likely to interest medical students at the present moment. The subject of medical education is just such a question. The address of Dr. P. W. LATHAM at St. George's Hospital and that of Dr. J. W. TAYLOR, Professor of Gynæcology in the University of Birmingham, at Charing Cross Hospital, form respectively an exposition of the great principles of medical education, and of the moral force which must actuate the student himself, and without which the most perfectly equipped school and the wisest and most efficient teachers will fail to produce good results. These are the two main points with which the introductory lecturer has to deal or between which he has to take his choice of theme. He may either deal with the methods and details of medical education and press his views on students and teachers alike, or he may appeal to all that is earnest and high-minded in the students before him and throw upon them the duty of working out their own teaching, making the best of their actual opportunities, and realising the very highest ideals of life and work which are possible to them.

Dr. LATHAM speaks with authority on the methods of study and of education. He reminds his hearers that more than a quarter of a century since he tried to introduce improvements into medical education, taking this journal as the medium of his views. He advocated two important changes—firstly, the promulgation of schedules limiting the range of examinations in each subject, the questions within that range to be searching and complete; and secondly, the abolition of certificates of attendance on lectures, with the provision that when a student presented himself for public examination he should bring with him certificates from his teachers of having gained sufficient knowledge to justify him in submitting himself to test. We supported these proposals at the time and to a certain extent they have been adopted. The General Medical Council in the following year passed two resolutions recommending, firstly, that in the case of certificates presented before admission to the examinations of the several licensing bodies, each should include a statement from the teacher or teachers that the candidate had satisfactorily attended examining classes from time to time held on the subject of study to which the certificate related; and, secondly, that it is desirable that in several of the subjects of examination—e.g., botany, zoology, chemistry, and materia medica—the scope should be limited and defined. Unfortunately, in accordance with a bad habit of the General Medical Council, it went over the same ground in the following year and ended with a resolution instructing the Registrar to ascertain what the licensing bodies thought of the recommendations and how far they had adopted them. To a certain extent, no doubt, the changes advocated by Dr. LATHAM have been adopted. But the reform is still incomplete. The testimony of the teacher to the work of

his students counts still for little or nothing in their examinations by the licensing authorities. Long and systematic courses of lectures still take up time which should be spent in practical and clinical work. Dr. LATHAM's caution against the tendency to cram too much undigested science into the medical student without reference to its use or applicability in medical problems deserves much attention. It may or it may not be an advantage that 50 per cent. of those who register as medical students at Cambridge never proceed to the degree of Bachelor of Medicine. But so large a defection goes far to raise doubts as to the system and to prove the justice of Dr. LATHAM's view that too much time may be spent by medical students over the preliminary sciences. The General Medical Council requires students to devote five years to medical study. Dr. LATHAM tells us that few at Cambridge take less than seven, and many eight years or more. It is highly probable that under such a system years spent in the earlier and preliminary subjects tend to exhaust a student's mind and to distract and unfit him for the real end of all his labours—that of acquainting himself practically with disease and all the devices of medicine and surgery for its relief. The practical and the scientific element in medical progress, as Dr. LATHAM shows, are equally essential. But it does not follow that they should be equally present in every member of the profession. It is impossible that they should be, and that is the most perfect medical education which includes as much of the scientific element as is necessary for eminently practical purposes.

Dr. TAYLOR's address, eloquent in tone and lofty in thought, cannot have failed to make an impress upon his audience. The young man who begins life, and especially medical life, without some reflections as to its meaning, its purposes, its risks, and its probable results to himself and others is not to be admired. We venture to believe that such young men are few and getting fewer. Modes of faith vary much in these days, but we all have the inward respect for character rather than intellect of which Dr. TAYLOR speaks, and we believe with him that it is character—the force and influence of right-mindedness—which determines true success. We are reluctant to see so much evil in modern society as Dr. TAYLOR sees, but we fear he has not exaggerated. Every medical student should read this address for his own sake and for the good to others which it may inspire him to do. If the nation is to be saved from the vices which proved fatal to older civilisations it will be largely due to the teachings of medical science—of those, to use Dr. TAYLOR's words, "who will be the doctors and advisers of the future generations and who may do much by steadily honouring and upholding higher ideals of individual, family, and national life to infuse a new and healthier spirit into the coming age." Dr. ARTHUR P. LUFF, in opening the school of the Pharmaceutical Society, of which he was a student 27 years ago, confined himself chiefly—as was natural—to an appreciation of the work of the Pharmaceutical Society. Most medical men will agree with him in thinking that there is a decline in the art of prescribing and of ordering suitable remedies for morbid conditions,

and will not differ from him in believing that the fact is partly due to the inadequate teaching of prescribing at the medical schools of so many of our large hospitals. The explanation of this is to be found in a decline of faith in the importance of drugs in the treatment of disease. The interesting subject of the obligations of a medical student to his hospital was handled by Mr. T. H. KELLOCK in his introductory address at the Middlesex Hospital, and he did not evade describing, if he did not altogether define, the duty of the hospital to guard against any abuse of its beneficent functions to the detriment of the very practitioners whom they educate. The fact that the use of drugs is imperfectly taught at our medical schools is a thing for teachers to ponder over—we cannot expect the hardly-worked students to insist upon more lectures. But students cannot learn too early the meaning of hospital charity. If they begin by appreciating the great work which goes on around them they are sure to fulfil their duties in a proper spirit.

### Peculiar Methods of Suicide.

THE subject of suicide presents many points of interest from a psychological standpoint. The question of whether or no the deceased was insane naturally stands foremost, but we do not intend to discuss this matter now; suffice it to say that there is a growing tendency for a coroner's jury to return a verdict of "Suicide during temporary insanity" rather than one of "*Felo de se*." In some instances there seems to have been a condition allied to "double consciousness," the person being sane shortly before and shortly after the act and yet unable to remember anything concerning the attempt on his life. For instance, a young woman jumped from the suspension bridge at Clifton and fell about 300 feet; her clothes acted as a sort of parachute and she was picked up alive and none the worse for the fall except for a few bruises. On being questioned she stated that she remembered nothing of her actions for some hours before she walked to the bridge and until she found herself in the infirmary. In other cases the act has apparently been due to some sudden, irresistible impulse for which no reason can be given.

It is well known that an insane person bent on taking his life will often adopt strange ways of carrying out the act and will wait an opportunity of adopting the measure which he has decided upon; thus a man has been known to swim across a river in order to throw himself under a train. Occasionally, however, most extraordinary methods have been chosen. In THE LANCET of Sept. 14th, 1901, we published a case of suicide in which the wounds were inflicted in the back of the neck, and in our issue of Sept. 28th, p. 876, we were reminded that we had described two similar cases some years before. More than one case is on record in which the entire larynx had been self-removed. One of the most extraordinary cases of this kind was recorded in the *Boston Medical and Surgical Journal* some 20 years ago, in which a man determined to guillotine himself. He constructed an apparatus by which a heavy axe-blade was held in place by a can of water. In the bottom of the can was a hole which allowed the water to run slowly out and when a certain amount had escaped the axe-blade was liberated.

The operator laid his head on some support, so that the axe would strike him on the neck, and placed a dish of ether in such a position that he would inhale it and so become unconscious before he was decapitated. The axe fell as he had intended. A strange attempt at suicide has been much quoted from our columns. A man placed the point of a dagger against the skull in the frontal region and then drove it into his brain by a blow from a mallet. The blade, which was four inches long, was driven in up to the hilt; but assistance came on the scene and the dagger was ultimately removed, the patient making a perfect recovery. A still more peculiar method of self-destruction was adopted by a man whose case was recorded in the *Medical Times and Gazette* in 1878. A man drove into his head two stone-chisels, each being eight and a quarter inches long and three-eighths of an inch in diameter, using for the purpose a wooden mallet weighing 2½ pounds. One of the chisels was driven through the head from right to left, entering in the right temporal region and emerging in the left nearly in a direct line; the other chisel was driven into the centre of the forehead, penetrating half an inch into the frontal lobe. After inflicting the injuries the man approached a glass door, through which he was seen by two persons. He tried to open the door but failed. When the door was broken open he walked a distance of 40 feet with but little aid, and was able to talk. The chisels were withdrawn with much difficulty and he died about five hours afterwards. In a case recorded in the *British Medical Journal* in 1881 by Mr. A. D. H. LEADMAN a man committed suicide by placing a dynamite cartridge in his mouth, lighting the fuse, and then awaiting the explosion. Great injury to the surrounding parts naturally ensued, but nevertheless the man lived two hours.

Drowning is a mode of suicide frequently resorted to both by men and women, but the mode of carrying out the act does not always consist in simply jumping or walking into the water. A case was recorded in THE LANCET of Sept. 1st, 1877, in which drowning was accomplished by simply plunging the head into a basin of soup, and in another instance a woman broke the ice on a pond, thrust her head through the hole, and so perished. Drowning may take place in quite shallow water. In many such cases death has been the result of accident, but Dr. DIXON MANN from his experiences considers that it is usually suicidal. Although homicide is frequently committed by throttling with the hands suicide in this way is, of course, exceedingly rare. A case, however, was recorded in the *Zeitschrift für Medicinische Beamte* of a woman, aged 40 years, who suffered from melancholia and who had previously made several attempts to commit suicide. She was found dead crouched in her bed with both hands compressing the throat; death had undoubtedly ensued from throttling. Death from strangulation by hanging is common, but sometimes a noose is used in a different way, the active strength of the suicide supplying the force that is usually supplied by his passive weight. An insane patient, upon whom Professor BOLLINGER<sup>1</sup> performed a necropsy, had succeeded in ending his life by strangulation of this sort.

<sup>1</sup> Friedrich's Blätter für Gerichtliche Medicin. Part I., 1889.

The body was found lying on the back with the right foot pressed against a bedpost. Round the neck was a loop-knot made of a bed-sheet torn in two, one end of which was attached to one of the bedposts. The deceased by pressing his foot against the opposite post had drawn the noose tight and so maintained it, thus bringing about strangulation.

Suicides occasionally select particularly painful means of ending their lives. For instance, in a case related by Mr. L. E. W. STEPHENS in the *Bristol Medico-Chirurgical Journal*, 1888, a man suffering from melancholia was seen with a red-hot iron rod about two feet in length, the cool end of which was against the wall and the heated end against his abdomen. He was interrupted in this attempt but not long afterwards he made the iron white-hot and succeeded in thrusting it four or five inches into the abdomen. In yet another case the dead body of a man with extensive burns was found lying on an iron bedstead. A burnt candle was beneath the bedstead. From papers in the room it appeared that the man wished to prove that suicides were not cowards, and he had adopted the following awful method of terminating his life in order to prove his theory. He had laid on the bed over the lighted candle, rising from time to time to record his sensations and then resuming his position on the bed. Many cases similar to the above, all of great medico-legal value as demonstrating what suicides may accomplish in the way of inflicting injuries upon themselves, are recorded. On superficial examination homicide may be suspected, whereas other evidence may conclusively prove the case to be one of suicide. Doubtful cases of this kind need the greatest care on the part of the examining practitioner, for on his evidence may depend in a great measure the verdict of the jury.

## Annotations.

"Ne quid nimis."

### LOOKING BACK.

THE occurrence this year of Oct. 5th, the date upon which THE LANCET made its first appearance, upon a Saturday has suggested to us that it may be interesting to our readers if we furnish to them from week to week, under the above heading, short extracts from the corresponding numbers of THE LANCET of 78 years ago. During that interval great changes have taken place and medical knowledge has advanced by leaps and bounds. In these ever busy days, however, it is good sometimes to pause awhile, to look back, and to consider the work of our forefathers and their views with regard to the profession and its place in the world. We cannot, perhaps, more fittingly commence "Looking Back" than with the Preface to the first number of THE LANCET, published on Sunday, Oct. 5th, 1823. We cannot say what the writer of those words would think of the present issue of the journal which he founded. But we venture to hope that his shade may view with some approbation the part that THE LANCET has played with regard to "acquirements in Medical learning." Although we fear we have not been successful in maintaining the exclusion of "the semibarbarous phraseology of the Schools,"

the rapid progress of medical science rendering such a course all but impossible, we have endeavoured to the best of our ability to cultivate "plain English diction." In one respect we must confess that THE LANCET has failed to keep to the promise of its Preface. The last paragraph says, "In conclusion—we respectfully observe, that our Columns will not be restricted to Medical intelligence, but on the contrary we shall be indefatigable in our exertions to render 'THE LANCET' a complete Chronicle of current Literature." In the course of 78 years Medicine has become an exacting mistress, claiming every inch of our space, notwithstanding the enormously increased size of the volumes. It will be noticed that the first number was issued on a *Sunday*; this continued to be the case up to and including the issue of Sunday, March 28th, 1824, after which Saturday became the day of publication. With these few words of explanation we refer our readers to "Looking Back" (p. 936).

### A MINISTRY OF PUBLIC HEALTH.

THE Eleventh International Congress of Hygiene is to meet next year at Brussels. As these congresses are the largest and the most representative and influential gatherings held for the purpose of pressing forward sanitary reforms it is but natural that urgent and practical proposals should be submitted to them. Among these proposals the desirableness of creating Ministries of Public Health has more than once been suggested. At most, if not at all, the International Congresses several speakers have urged that the care of the public health should not be relegated to a mere department of the Ministry of the Interior, or, as in England, to the Local Government Board, but that it should constitute a Ministry in itself with a responsible Minister of Public Health at its head. From time to time we have received various communications on this subject, and recently Dr. F. G. Bushnell, medical officer of the Plymouth Public Dispensary, has written to us protesting that in certain colonies and countries the organisation of the national public health services is more thorough than it is in England. This proves that the value of scientific measures for the protection of the health of the communities in question is well appreciated. The high character, Dr. Bushnell goes on to say, of the work of our medical officers of health emphasises the need for more systematic action in such matters as the appointment of county medical officers, and the improvement of the conditions of the tenure of office of district medical officers. Then there are the questions of State aid for the creation of sanatoria for the treatment of tuberculosis, of public health laboratories, and of organising popular education on the principles and methods of preventing disease, on the feeding and rearing of infants and on domestic hygiene. The powerful associations interested in public health matters, it is maintained, should unite to press upon the next International Congress of Hygiene the importance of the formation of a Ministry of Public Health. To all this we would add that mere suggestions, however excellent, do not suffice. Someone must take the initiative. A proposal which had previously been approved by several associations, or, better still, by a national congress, would have more weight than if it were brought forward by an individual member. It is also absolutely necessary that any movement to be followed by debate and resolutions at the International Congress should be presented in the proper manner. First, a paper must be written explaining the case, and this not merely from the British point of view but also from that of at least some other nationality. Then a summary, or, better still, the whole of the paper, should be translated into French and German, together with the resolutions to be

submitted to the Congress. Dr. Putzeys, delegate of the Belgian Government, who invited the next Congress to meet at Brussels, will probably act as the general secretary. By applying in good time the papers and the proposal to create in all countries Ministries of Public Health might be included among the official subjects of discussion, and the whole question might be submitted to the delegates before the Congress met. If so, the vote which would be subsequently recorded would have much more weight. Those who feel sufficiently earnest in the matter must take the necessary trouble to do this and not content themselves with the mere expression of a pious wish.

#### THE CAUSATION OF SLEEP: A THEORY.

A CORRESPONDENT writes to us suggesting a new theory as to the causation of sleep—namely, that a gland or certain glands in the system secrete a narcotic substance; that this substance is stored in the gland or glands until at definite times—mainly influenced by habit and “tiredness” of the individual—it is thrown into the circulation and thereby causes the phenomenon of sleep. Further, he suggests that sleep continues as long as the supply of the “natural narcotic” is kept up—until the latter is so far attenuated in, or wholly abstracted from, the blood by the excreting organs. As he truly suggests, however, no direct evidence of the correctness of this theory is yet to hand, but he refers to a lately discovered fact that the urine of health secreted in waking hours always contains a narcotic substance, and he urges this point in support of his theory. The existence of such glands is difficult to deny, but we cannot say that we think the theory a very plausible one, neither can we agree with our correspondent when he says: “It [the theory] has this one merit, at any rate—it can easily be put to the test in the laboratory.” In the Croonian Lectures for 1899 Professor J. B. Bradbury gave a most careful analysis of the various theories of the physiology of sleep which had hitherto been advanced and stated that owing to the differences of opinion of observers regarding the exact condition produced by hypnotic drugs, he found it impossible to draw a satisfactory conclusion regarding their mode of action or the cause of sleep. We are far, however, from wishing to detract from the merits of a theory because it has not been put to the test, but at the same time we are of opinion that our correspondent will find considerable difficulty in putting to the test his supposition of a natural hypnotic secreted from special glands. Sir T. Lauder Brunton has pointed out that opium will keep a person awake if he wishes to be wakeful, and conversely will make him sleep if he wishes to sleep, which would seem to show that sleep is in some measure under the control of the will.

#### REPORT ON THE PLAGUE AT GLASGOW.

WE are pleased to see that the Corporation of Glasgow have issued an illustrated volume containing the official report on the cases of plague which occurred in that city last year. This report has been prepared by Dr. A. K. Chalmers, the medical officer of health, on whom rested the responsibility of coping with the outbreak. Most of the information which this volume contains, as also the photographs of some of the cases, have already been published in these columns. It is nevertheless useful to have these details in a compact form, for they are thus more ready at hand for reference. There is also a “spot” map of the localities affected showing that the great majority of cases occurred in the poverty-stricken and overcrowded districts on the south side of the river Clyde. No one can have visited these wretched streets and habitations without being painfully impressed by the squalid, neglected, ragged, barefooted, and dirty appearance

of a large section of the population. It is well, under such circumstances, with typhus fever not yet eradicated and with plague still threatening, that the Corporation of Glasgow should have taken the initiative of convoking a Conference on the Housing of the Poor. After the warning conveyed by plague it is to be hoped that such action will not be limited to the discussion but that something really effective will be done to house in a more civilised manner the residuum of the population.

#### “THE RED BADGE OF COW-POX.”

A HUNDRED years ago, when Jenner's vaccination doctrine was being publicly preached against and opinion rose to an almost fanatical frenzy against the heinous novelty of inoculation, he would have been a daring prophet who foretold the day when the woes of a “vaccination arm” would be commonly regarded as a fit subject for jocular treatment. To-day that is to a large extent the aspect of the matter that appeals to people. There is, of course, the anti-vaccinationist who, like all faddists, is deficient in a sense of humour, just as he is deficient in the power to judge his subject fairly from a broad view of every side. For him reasonable argument is dulled by prejudice, and the written evidence of men who lived before and during the introduction of vaccination is no more convincing than the weight of logic. Happily, this class of blind disbeliever is much diminished, even as his cousin germane the conscientious objector will diminish before the diffusion of definite knowledge and the results of experience. A limited advent of small-pox such as we are now witnessing in London has, at any rate, this advantage, that it leads a large number of people to get definite information on the subject of vaccination and enables medical men to read a lesson to which at other times the public may turn a deaf or indifferent ear. The laziest or least curious individual becomes interested to know the truth about preventive measures when small-pox is next door. The general experience of practitioners at the present time, we may fairly believe, is that there is, despite the conscientious objector, a wide and growing tendency to familiarity with the *rationale* of vaccination; it is taken as a matter of course and even a joke is made of its inconveniences. That the inconveniences in the case of an adult who “takes well” are not to be disregarded many of our readers will doubtless be aware from painful personal experience. This side of the question appears to have appealed forcibly to members of the Stock Exchange who have been wearing a red band on the sleeve of the inoculated arm as a beacon to warn off the friendly grasp which under the circumstances becomes too painfully warm a salutation. Some men, less trusting in the powers of observation or restraint on the part of their fellows, have exercised their minds to find a site for vaccination which would be safe from jostling. The leg has thus been freely chosen in preference to the arm, but sometimes the disabilities of the two are nearly matched, as in the case of the pianoforte teacher who complained that if vaccinated on the arm she could not play with her pupils and if on the leg she could not reach them to play with. Of the objections to vaccination, other than conscientious, a most amusing treatise might be constructed, though we doubt whether it would contain many instances so wildly inconsequent as the asserted objection which reaches us from a country correspondent. He relates the remarks of a farm labourer who believed that vaccination would involve peculiar danger to his own children because their grandfather had been tossed by a bull. At any rate, this man had some vague notions of the connexion of cow-pox with vaccination. It may have been curious stories such as this which turned a paragraph writer in the *Globe* to vaccination

for a playful headline. "*Arma virusque cano*" he began, and explained that he was talking of arms and the vaccination mark! Among educated people, then, it may fairly be taken that vaccination is so generally accepted and familiar that even its inconveniences are a laughing matter. After the present augmented activity in vaccination we may hope that there will be few persons in Great Britain to whom its benefits are not obvious and by whom its defects will not be treated in this same spirit of pleasant contempt.

#### ANNUAL MEDICAL SERVICE AT ST. PAUL'S CATHEDRAL.

THE annual medical service at St. Paul's Cathedral organised by the Guild of St. Luke will take place this year on Thursday, Oct. 17th, the Eve of St. Luke, at 7.30 P.M. As in past years many members of the medical profession have signified their intention of attending in academical robes. The arrangements of the service this year have been considerably modified with a view to making it simpler and brighter. The sermon will be preached by the Rev. Canon Gore, and the music will be rendered by the London Choir Association, the choir being conducted by Dr. H. Walford Davies, organist of the Temple Church. Admission to the spaces under the dome will be by tickets only.

#### ROYAL VETERINARY COLLEGE.

THE introductory address to the students beginning their professional studies at this College was delivered by Professor E. M. Crookshank, the chair being taken by Mr. Albert Brassey, M.P. Professor Crookshank spoke very highly of the teaching and equipment of the college, of the advantages of the veterinary profession as a career, and of the value in many occupations of a veterinary training. He urged the necessity of the importance of original research in veterinary work, and as an illustration of the great need for further investigation he instanced the subject of tuberculosis. He reminded his hearers that at the recent Congress on Tuberculosis the relation of the bovine to the human malady was prominently brought forward in an address given by Professor Koch. It was instructive and encouraging to the veterinary profession that some of the researches which created so much interest at the congress were those undertaken in different veterinary colleges. Professor Koch's experiments had been carried out during the past two years with the coöperation of Professor Schutz at the Veterinary College of Berlin. Professor Crookshank then referred at some length to Professor Koch's experiments which led to the conclusion that human tuberculosis differed from bovine and could not be transmitted to cattle, and Professor Koch further announced that whether man was susceptible to bovine tuberculosis at all was not yet absolutely decided. Professor Crookshank agreed fully with Professor Koch that if infection to human beings occurred at all it was very rare, but he could not accept the statement that human tubercle could not be experimentally inoculated in bovines. He also felt very strongly that Professor Koch's dictum that preventive measures were not advisable was a singularly unfortunate one. It conveyed the impression, as Dr. Hueppe had pointed out, that Professor Koch would concede to dairymen and milk-sellers the right of selling tuberculous milk. Professor Crookshank felt justified in disagreeing with Professor Koch in these points because in the course of an inquiry in 1888 which he had conducted on behalf of the Board of Agriculture he made an experiment which proved that a healthy calf could be successfully inoculated with human tuberculous sputum. Other investigators in England and America had confirmed this result. Professor Crookshank was of opinion that human and bovine tuberculosis were distinct varieties of the same disease. Man was not the natural soil of bovine tuberculosis, and the attempts

to graft human tubercle in cattle would not be uniformly successful, and experiments which did not entail the direct insertion of the virus into the tissues might fail entirely. Another instance which proved that the different nature of the soil must always be taken into account was the variolation of cattle. There was the possibility that inasmuch as human tuberculous virus can be grafted on the cow there may also be instances of invasion of the human tissues with bovine bacilli, but Professor Crookshank was quite in agreement with Professor Koch that such an occurrence could only be quite exceptional. If it were the rule the inhabitants of every country in the world in which bovine tuberculosis was prevalent must have been decimated by tuberculous disease owing to the frequency with which tubercle bacilli occur in milk, cream, butter, and cheese, and the quantity of meat derived from tuberculous animals. Professor Crookshank then made some remarks on meat inspection and maintained that a carcass should be condemned when the disease was generalised; but if the carcass was well nourished and the meat healthy in appearance the existence of small local deposits of tubercle in the organs was not a sufficient reason for condemning the flesh as unfit for food.

#### HOP-PICKERS AND SMALL-POX.

ON Saturday last, Sept. 28th, Dr. G. Newman, medical officer of health of Finsbury, informed the medical officer of health of the County of London that certain cases of small-pox had been found among hop-pickers whose London home was in Finsbury and who had returned to London from Bodiam in Sussex. It was also stated that other persons at the farm where they had been employed had had eruptions similar to those found upon the persons who had returned, and that all of the hop-pickers employed on the farm would return on that day. Prompt measures were taken for medical men to meet the trains by which these people might arrive, the medical officers of the London County Council and of Finsbury and the chairman of the Sanitary Committee of Finsbury, Mr. Evan Jones, M.R.C.S. Eng., taking part in the work. All the hop-pickers arriving during the afternoon and evening at New Cross, London-bridge, Waterloo, Cannon-street, and Charing-cross stations were, as far as was practicable, examined, and the addresses of persons coming from the farm were taken. Five persons actually suffering from small-pox were detained by Mr. Evan Jones (who undertook to watch at Cannon-street station) and were sent to the hospital ships. As a piece of prompt action, rendered possible by the coöperation of the county and borough officers, we may speak with much satisfaction of the procedure adopted; and the fact that actual cases of small-pox were found among the travellers will justify to the most critical every step that was taken. The incident, however, serves to show how little anyone can reckon upon not being exposed to small-pox and how the only actual safeguard is to render each individual insusceptible to attack. Small-pox was not known to exist at Bodiam and the fellow travellers of the sufferers were certainly unconscious that their companions were suffering from this disease. It will be interesting to observe what effect the return of the hop-pickers to London has on the prevalence of the disease. It is too much to expect that no proportion of the people at Bodiam who were associated with the sufferers on the farm, and who travelled with them in crowded carriages to London are incubating small-pox. As far as it has been possible to do so the addresses of people coming from this farm have been ascertained, and where this has been done they will no doubt be kept under observation; but small-pox in the metropolis will in all probability receive some increment from this source and there is a chance that the disease will be carried into homes where the risk of spread will be especially

great. Whatever the result is there will be the satisfaction that every step was taken to limit the mischief as far as this could be done. Among the factors conducing to the spread of small-pox at the present time is the difficulty of distinguishing it from chicken-pox. It is stated that the disease among the hop-pickers on the Bodiam farm was regarded as chicken-pox and hence the circumstances of which we have given account. We note with satisfaction that the Borough Council of St. Pancras are proposing to require the notification of cases of chicken-pox, and the adoption of this course will, no doubt, go far in that district to meet the difficulty which we mention.

#### CHARACTERISTIC HEADACHE IN TUMOUR OF THE CEREBELLUM.

At the meeting of the Société Médicale des Hopitaux of Paris on June 14th M. Pierre Merklen pointed out that the headache of cerebellar tumour may be characteristic. He finds that the pain is principally occipital, but may be also frontal or occupy the whole head. At first it is intermittent, then it becomes continuous, but exacerbations, which may be excruciating, occur on exertion. Further, the headache is accompanied by rigidity of the neck and retraction of the head—an attitude which is assumed because every movement intensifies the pain. Finally, the headache is little influenced by drugs, but, curiously, is subject to temporary remissions under the influence of "suggestion"—of any new treatment, for example, or of isolation or any exercise of medical authority. The cause of the headache is intracranial tension from hydrocephalus of the ventricles. The tumour lying under the tentorium cerebelli compresses the veins of Galen and causes dropsy of the ventricles. Movements and efforts increase the intracranial tension and therefore the headache. The only treatment is removal of the tumour or palliative trephining. The following case confirms the preceding description and explanation. At the beginning of September, 1894, a man, aged 28 years, in good health, was suddenly seized for some minutes with pain in the forehead and nape of the neck. The pain returned every morning and was always provoked by exertion. In October the spleen was found to be enlarged and the meningeal streak could easily be produced. Meningeal tuberculosis was suspected, although there was no pyrexia or other symptom of the disease. In November there were violent paroxysms of headache on exertion and the patient held his head retracted. The idea of intracranial tumour was suggested by M. Brissaud, M. Raymond, and M. Rendu who saw the patient in consultation with M. Merklen, but the absence of other symptoms did not allow a definite diagnosis. One day the patient complained of violent pains in the abdomen. As he had become hysterical this symptom was thought to confirm the diagnosis of neurosis. Accordingly he was isolated in a hydropathic establishment. Great improvement took place in the first week, though the stiffness of the neck persisted. Then the paroxysms of pain recurred and were accompanied by vomiting. In January, 1895, they became more frequent and he would scarcely leave his bed. Apart from the paroxysms he complained of continuous occipital and frontal pain. At times his gait was like that of a drunken man. There were no ocular signs. He improved for a few days and returned to his home; then all the symptoms became aggravated and he threatened to commit suicide. Anodynes, including morphine, were useless and only inhalation of ether gave relief. On Feb. 23rd M. Terrier made a horse-shoe incision from the left ear to the occiput and trephined the skull. When the dura mater was opened by a crucial incision the brain bulged out. It was punctured with a needle, but no fluid escaped. The skin and periosteum were sutured, but the dura mater was not. Improvement was immediate and the patient was free from pain for

five days. Then he began to have pain in the trephined area. On March 3rd union of the wound was complete, but in the position of the cicatrix was a fluctuating swelling of the size of an egg. This enlarged and became distended until some liquid flowed away from it. Puncture gave exit to 250 grammes of clear fluid and the patient was relieved, but on the next day it was again distended and the vomiting and pain reappeared. On April 16th puncture gave exit to 500 grammes of cerebro-spinal fluid. From this date puncture was performed every other day. The patient wasted and always complained of pains in the temporal region and in the trephined area. On June 23rd he became comatose and died. The necropsy showed a tuberculous tumour of the size of a mandarin orange in the left lobe of the cerebellum. The swelling at the trephine opening was formed by a hernia of the dilated left lateral ventricle, the wall of which was very thin. M. Merklen, who insisted on the importance of *céphalée d'effort avec raideur de la nuque* as a sign of cerebellar tumour, referred to another case in which this sign proved diagnostic. He saw in consultation a man who for several months after a carriage accident suffered from vertigo and headache and who at last became somnolent. M. Merklen ascertained that the headache appeared on, and was intensified by, exertion and was accompanied by a rigidity of the neck. Operation showed a serous cyst of the cerebellum, the evacuation of which proved a radical cure.

#### AN INGENIOUS ADULTERATION.

ANYONE may adulterate butter, whether it be for his own consumption or for that of his neighbours, but if he deals in the adulterated article he must follow in so doing the conditions laid down in the Margarine Act—he must not sell it as butter and he must not, *a fortiori*, sell it as "pure butter." The firm of Pearks, Gunston, and Tee, Limited, who claim to have a very large number of places at which they sell their goods, were summoned in July last under the Sale of Food and Drugs Act for selling that which was not of the nature, substance, and quality of the article demanded by their customers; that is to say, for selling as butter a substance containing more than the 16 per cent. of moisture which is recognised as a lawful factor in the butter of honest commerce. They were further charged in other summonses under the Merchandise Marks Act with applying a false trade description to their goods. In July the full hearing of these summonses was adjourned owing to the defendants desiring to await and abide by an appeal then pending which has now apparently been decided adversely to them, for they have appeared again at the police-court and have been duly fined. The nature of the appeal we need not discuss, for the facts of the case against Messrs. Pearks, Gunston, and Tee, Limited, hardly seem to us capable of raising legal discussion; their methods, however, as described in July, were sufficiently ingenious to be worth recalling. It was their practice to purchase large quantities of colonial and foreign butter which, owing to the method of its preparation and the exigencies of its market, contains considerably less moisture than ordinary English butter, and into this they used to force milk by softening the butter and blending the two together in huge churns, adding a little borax in compensation as a preservative. It was stated before Mr. Curtis Bennett that by this process as much as 10 quarts of milk could be added to a hundredweight of butter, and a moment's calculation by those familiar with the weight of liquids will show that this means the increase of a hundredweight of butter by more than 20 pounds avoirdupois, with an addition of profit to the vendor equal to the difference between the price of the added milk and the price of a quantity of butter of

similar weight. We have only to assume, as we safely may, that the foreign butter purchased was considerably cheaper than pure butter made in England to see that the compounded article sold in pound and two-pound packets as "Pearks's Pure Butter" formed a highly profitable article of trade to its vendors. That the same substance may continue to be dealt in with profit in the future we do not gainsay, but it will have to be sold under a true description and not to those who ask for "butter," while we may be permitted to add a wish that the energy and ingenuity of merchants such as those mentioned could be devoted to the raising of the quality of English products rather than to lowering that of food substances produced with such exemplary skill and economy by our colonies and our foreign neighbours.

#### THE NEWLY-ELECTED LORD MAYOR OF LONDON.

THE election of London's chief magistrate does not often present any feature of notable instance from a medical point of view, but the ceremony of Sept. 28th, a ceremony transferred to the eve of the feast of Michaelmas on account of the feast itself falling on a Sunday, had especial interest to every member of our profession and a double interest to those who chance to be Etonians. For on Sept. 28th, 1901, Alderman Sir Joseph Cockfield Dimsdale was elected to fill the office of Lord Mayor of London for the ensuing year. Sir Joseph Dimsdale, who is the first Etonian to fill the civic chair for 130 years, comes of an old Essex family whose members have, as a rule, belonged to the Society of Friends and one of the most renowned of whom was Thomas Dimsdale, M.D., who was born in 1712, educated at St. Thomas's Hospital, and who, in 1767, published a book entitled "The Present Method of Inoculation for the Small-pox." This passed through many editions and in 1768 Dimsdale was invited to Russia by the Empress Catherine for the purpose of inoculating herself and her son, the Grand Duke Paul. There were ignorant persons in Russia in those days as there are now in this country, and in case of any untoward result the Empress had relays of post horses ready all the way from St. Petersburg to the frontier for the safe conveyance of Dimsdale out of the empire. Both patients, however, did well and Dimsdale received the honour of being made a baron and a councillor of State, together with a sum of £10,000 down, an annuity of £500, and £2000 for expenses. In 1784 Dimsdale was again summoned to Russia to inoculate the Grand Duke Alexander and his brother Constantine. Inoculation received its death blow on the introduction of vaccination, which brought about protection with far less risk, but it is interesting to note the election of a Dimsdale to the highest civic post in London at a time when the city is suffering from an outbreak of small-pox. We offer him our congratulations upon the honour to which he has been elected.

#### THE PATHOLOGY OF SPORADIC CRETINISM.

In the September number of the *American Journal of the Medical Sciences* Dr. Frederick A. Packhard and Dr. Alfred Hand of Philadelphia give an account of sporadic cretinism and endeavour to throw some light on the pathology of this obscure affection. The patient observed was a child six years of age who seemed to be weak-minded and undeveloped. He was admitted to hospital in December, 1897. There was nothing in the family history which had any bearing upon the case, and two other children born respectively before and after him were perfectly healthy. He grew very slowly and was weaned at the age of 20 months. When a few weeks old he had an attack of asphyxia and it was noted that the tongue was large and inclined to protrude. He was always intensely constipated, the bowels never moving more than

three times a week. At six years of age he was only 81 centimetres (32 inches) high, unable to talk or to understand what was said to him, and perfectly apathetic, lying back among the pillows and not moving except for an occasional slight rolling of the head. The skin was of a peculiar yellowish-white colour, the features were heavy and doughy, and the eyelids were thickened and half-closed. The tongue protruded from the mouth, completely filling the orifice of the lips and being very doughy to the touch. The scalp was almost completely devoid of hair and the anterior fontanelle was widely open and pulsating. The neck was large and full and at its base was surrounded by a thick collar-like mass of doughy consistence. "The face was distinctly pig-like and devoid of expression." The hands were pudgy and short, and the tissues of the arms felt as though they were the seat of solid œdema. The abdomen was quite "aldermanic," and there was a large umbilical hernia. The case was diagnosed as one of sporadic cretinism and placed on thyroid treatment (two grains of thyroid extract three times daily). During the second week improvement began to be noticed, and gradually he showed diminution of the collar of fat, and his general appearance and intelligence began to improve. His bowels also showed a greater tendency to move normally. Improvement continued for several months, and before October, 1898, he had begun to learn to talk and to understand much of what was said to him. His height had now increased by nine centimetres (three and a half inches), the anterior fontanelle was closed, the tongue was reduced in size and kept within the mouth, the abdomen was normal, and he laughed quite naturally. In November of that year he developed typhoid fever, the temperature rising to 104° or 105.5° F., with occasional elevations even higher. He became rapidly emaciated and died, "his powers of resistance being from the outset almost nil." The necropsy, performed three hours after death, showed a large and persistent thymus gland in the anterior mediastinum and extending upwards one and a half centimetres (three-fifths of an inch) into the neck. The liver was fatty. The Peyer's patches of the small intestine were ulcerated and in the superior cerebral sinus there was a yellow thrombus. Nothing important was noted in the brain except that the pituitary body was considerably enlarged, measuring 13 by seven by five millimetres. The thyroid acini showed deficiency of colloid secretion, and the liver showed a universal fatty degeneration of the parenchyma with foci of necrosis. A most peculiar feature was a calcareous degeneration of the thyroid arteries, a condition undescribed before. Dr. Packhard and Dr. Hand agree with Dr. Byrom Bramwell<sup>1</sup> on the efficacy of thyroid medication in these cases, and think it possible that a deficiency of thyroid secretion coupled with disease of the thyroid arteries constituted the basis of the disease.

#### SUDDEN DEATH FROM A CLOT ON THE RIGHT SIDE OF THE HEART.

In the present number of THE LANCET we publish a case of some interest, in which sudden death occurred a week after an amputation. The death was preceded by severe dyspnoea lasting five minutes, and not unnaturally a diagnosis of pulmonary embolism was made; but at the necropsy, although all the pulmonary arteries were laid open, no embolus could be discovered. In the right side of the heart, however, was found an ante mortem clot about four inches in length extending from the auricle to the ventricle. If this clot were certainly ante mortem in origin, its presence would serve to explain all the symptoms, for the interference with the action of the tricuspid valve and the consequent

<sup>1</sup> THE LANCET, Dec. 10th, 1898, p. 1547.

tricuspid regurgitation would produce dyspnoea, as but a small quantity of blood would be sent onwards through the pulmonary artery. It is not probable that the clot was formed *in situ*, but it is far more likely that it developed in the right auricle and that some disturbance had detached it and had placed it in the situation in which it was found. If this be the correct interpretation of the conditions discovered post mortem the case is certainly extremely rare.

#### THE HANBURY GOLD MEDAL.

THE Hanbury gold medal for 1901 was presented on Oct. 1st to Dr. George Watt by the President of the Pharmaceutical Society. This medal, which was established as a memorial to Daniel Hanbury, is awarded biennially for high excellence in the prosecution or promotion of original research in the chemistry and natural history of drugs, the Council of the Pharmaceutical Society being the trustees of the memorial fund. On the same occasion the prizes of the society were distributed and the inaugural sessional address was delivered by Dr. A. P. Luff. This address appears in another part of the current issue of THE LANCET.

#### THE PRESIDENTIAL ADDRESS AT THE FRENCH CONGRESS OF ALIENISTS AND NEUROLOGISTS.

DR. GILBERT BALLET delivered the Presidential Address at the French Congress of Alienists and Neurologists, held at Limoges on August 1st, touching briefly on past achievements and indicating the directions for future advancement. He referred to the need of more vigour in method and more precision and delicacy in technique for the advancement of psychological medicine. One of the greatest achievements of the closing decade of the nineteenth century was the definite emancipation of the studies of normal and diseased "mind" from the thralldom of metaphysics. The progress of clinico-pathological research and neurological technique served to accelerate the movement. The most ingenious speculations of Plato, Descartes, and Leibnitz were superseded by the study of the brain and nervous system after the clinical, histological, experimental, and pathological methods now in vogue, and more light was thus shed on the subject than had been done by the systematic and philosophic dissertations written hitherto. The brain has, however, not yet yielded to us all its secrets. There remain regions and "areas" of the cerebral cortex of whose functions we are ignorant, and the connexions of the various nerve-centres and tracts in the mesencephalon and bulbo-spinal cord are not as yet fully explored. Clinical and experimental studies have shown that microbic infection as well as intoxication with alcohol, lead, and other poisons are capable of producing various forms of myelitis and states of delirium and mental confusion, but we are still ignorant of the cause of disseminated sclerosis (*sclérose en plaques*). While the facts of heredity have been diligently studied and collected, and its laws formulated, little is known as regards predisposition, our knowledge in the latter respect being still in the empirical stage. Inquiry into the etiology of disease has revealed to us definite agencies productive of mental disorder, such as syphilis as a factor of general paralysis and of tabes, and it is clear that when the causation is well recognised preventive measures can be adopted and the mischievous results thus diminished. Even gout, diabetes, and affections of the same class play a part in the production of neuroses, but it is especially alcohol which is the most potent cause of nervous and mental disease, and in regard to which our efforts should be mainly directed to prophylaxis. Many persons have suggested that feeble and crippled children should not be permitted to live, but Dr. Ballet does not think that

modern nations would wish to imitate Sparta in their treatment of these little unfortunates. By diffusion of knowledge and by our efforts to instruct public authorities and the people on the causation of disease and on the mode of prevention of diseases at their sources much may yet be achieved. Our solicitude for the infirm and the insane is shown by our provision of public hospitals and asylums for their accommodation and treatment, but we should not aid them to propagate a feeble, effete, and degenerate offspring which becomes a burden and a menace to the resources of a state.

#### THE CLEANSING OF PUBLIC VEHICLES.

DR. ALFRED GREENWOOD, medical officer of health of Crewe, read a paper at the recent Congress of the Royal Institute of Public Health at Eastbourne on the Need for Legislation in the Disinfection and Cleansing of Railway Carriages, and has drawn attention to his views in the *Times*. Referring to a resolution which was passed at the above-named Congress to the effect "that the attention of the Government be called to the danger to public health caused by the lack of frequent wet cleansing and disinfecting of railway carriages, tramcars, and omnibuses," he suggests that a committee should be formed to investigate the subject, which would be able to prove that the dust in such vehicles may be infectious and that sufficient care is not exercised in cleansing them. The committee would also consider the practicability of the following suggestions: (1) the fixing of cautionary notices in all railway compartments; (2) the imposition of penalties for infringing this rule; (3) the construction of railway compartments in such a way that the cushions and flooring should be detachable and that the cushions should be made of a less pervious material than that used at present; and (4) the wet cleansing and disinfecting of all railway compartments at frequent and regular intervals. The foregoing regulations would equally apply to tramcars and omnibuses. We cordially endorse Dr. Greenwood's suggestions, and the question of over-crowding might also be raised. We believe that the education of the public as regards public hygiene and the prevention of tuberculosis can be more easily accomplished by such measures than by the costly and elaborate method of notification, that to be of service must be general and not voluntary. In America penalties are imposed for spitting, but we are doubtful whether the time has yet arrived for adopting similar measures in this country; an exception might be provided for in the case of those offenders who persist in expectorating upon the floors of public vehicles in spite of notices and warnings. Objection has been taken to the smell of some disinfectants, but now no such excuse can be made, since many such bodies—e.g., formaldehyde—are free from odour. Voluntary cleansing of public vehicles would not remedy the matter; the systematic and frequent wet cleansing of them should be a compulsory measure enforced by legislation.

#### SMALL-POX IN LONDON.

WE refer elsewhere to the thorough manner in which the cases of small-pox among returning hop-pickers were dealt with by the medical officers of the various municipal authorities of London. With regard to other cases, on Sept. 30th there were six fresh cases notified; on Oct. 1st there were eight fresh cases; and on Oct. 2nd there were six fresh cases. Despite the efforts of the anti-vaccinationists reports from various quarters of the metropolis show that vaccination and revaccination are being carried out. The London School Board and the health authorities of St. Pancras have managed to get into a deadlock which in presence of the epidemic is peculiarly unfortunate. It will be

remembered that the London School Board gave a qualified permission to inspectors to enter the schools for the purpose of inspecting the children. Of course, no school board should have the power to prevent the health authorities from inspecting the children or the buildings under their charge. The clerk to the St. Pancras Board of Guardians wrote to the London School Board asking for the necessary permission for the vaccination officers to enter. The School Board replied that the local sanitary authority was the "proper local authority" mentioned in the School Board's resolution.<sup>1</sup> The clerk to the guardians thereupon applied to Dr. Sykes, the medical officer of health of St. Pancras, who wrote to the School Board informing that body that he had applied to the board of guardians and thereby, to save time, made application for permission for the entrance of the vaccination officers. The School Board wrote back that the board of guardians were not the sanitary authority but that the borough council were. The clerk to the borough council has replied that he has no authority, and so the matter stands over until Oct. 16th when the next meeting of the borough council is to be held. St. Pancras, be it remembered, is the centre of the outbreak.

#### THE PERIOD OF PUBERTY IN RELATION TO DISORDERS AND ANOMALIES OF DEVELOPMENT.

In the *Journal of the American Medical Association* of Sept. 14th Dr. V. S. Christopher, Professor of Pediatrics at the Chicago College of Physicians and Surgeons, has published a lengthy article dealing with the relation of physical mal-development to the liability to disease at the period of puberty. The investigation included a total of 6259 children—viz., 2788 boys and 3471 girls—who were examined in the Chicago public schools and who were mainly the children of American parents in comfortable circumstances. The physical measurements included stature, height sitting, weight with ordinary indoor clothing, endurance as measured by the ergograph, strength of grip of the right and left hands, and the so-called "vital" or respiratory capacity. A number of tables of the data thus collected were constructed and many interesting facts were obtained. Thus, as regards the growth of children it was seen that in the case of boys the growth-rate slowed down from infancy up to the age of seven years, that from seven to nine years of age the rate was uniform, and that from nine to 12 years a period of quiescence of growth again took place. From 12 to 17 years, however, the growth-rate was rapid and accelerated. The curve of growth for girls shows a less well-marked quiescent period from nine to 11 years of age, while the acceleration of growth begins at the age of 11 years—i.e., a year earlier than boys—and is more rapid at first, but of shorter duration than in boys. It is therefore shown that there is an exaltation of the vital processes of growth at the period of puberty in both sexes, commencing at 11 years in girls and at 12 years in boys, and that this period of accelerated growth is preceded by a period of quiescence. From a minute study of the physical variations or departures from the normal occurring during the period of puberty, Dr. Christopher considers that "while puberty is a period of great exaltation of life processes it is also a period of great individualisation. It is a time when the weak fail and the able forge to the front." While mortality is low during the epoch of puberty morbidity, or the tendency to disease or disorder, is high, the principal ailments being neuroses, psychoses, neurasthenias, cardiopathies, deformities, and anæmias. If growth takes place with unusual rapidity the capacity of the nutritive and assimilative functions is so taxed that the boy or girl is "on the borderland of physical insolvency, and

any excessive voluntary expenditure of energy may be followed by morbid symptoms." A rapid and irregular pulse, a dilated heart, and neurasthenia with a tendency to stooping may thus be developed. In one case, that of a neurotic boy who increased in weight with great rapidity, an epileptic convulsion followed every instance of excessive exertion—e.g., a 20-mile bicycle ride or a violent game at baseball. He was practically free from convulsions so long as he refrained from unusual expenditure of energy. Heredity may assist in the production of the disorders or defects of this period, but nutrition and rest also play an important part in the process. Some deformities, such as round shoulders and scoliosis, are among the results which may occur. Manifestations of neurasthenia, fatigue, and cardiac dilatation require for their proper management rest and improvement in general bodily nutrition; and where stooping and round shoulders occur shoulder-braces may be employed in conjunction with carefully regulated gymnastics. Dr. Christopher concludes that special medical supervision should be maintained over boys and girls during puberty and any disorders or anomalies of growth corrected as early as possible.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope, received at the Colonial Office on Sept. 25th, states that for the week ending Sept. 21st the cases of plague throughout South Africa numbered 0. The deaths from plague numbered only 1, and that a native at Port Elizabeth. The area of infection remained unchanged. As regards the Mauritius a telegram from the Governor, received at the Colonial Office on Sept. 27th, states that for the week ending Sept. 26th there were 33 cases of plague and 23 deaths from plague. As regards plague in Egypt during the week ending Sept. 22nd 10 cases and 7 deaths from plague have been reported throughout Egypt as follows:—2 cases and 2 deaths from Port Said, 3 cases and 0 deaths from Alexandria, 3 cases and 3 deaths from Mit Ghamr, 2 cases and 2 deaths from Benha. 1 case and 1 death at Port Said and 1 case at Alexandria occurred among Europeans; the remaining cases and deaths all occurred among the native population of the different towns.

#### DANGEROUS PARAFFIN LAMPS.

The dangers of cheap paraffin lamps have been known to everyone for some years. We demonstrated very clearly in our Commission upon Dangerous Paraffin Lamps which appeared in THE LANCET of Jan. 4th, 1896, the risks to life which follow upon the use of lamps of certain faulty patterns. The Home Office and the Education Department have now drawn up a number of suggestions for the care and use of lamps. The Education Department have embodied the suggestions of the Home Office in a circular which has been forwarded to managers of elementary schools so that they may impress the suggestions on their scholars. The suggestions are as follows:—

1. The wick should quite fill the wick-tube, without having to be squeezed into it.
2. Before using, the wick should be dried at the fire and then immediately soaked with oil.
3. Wicks should be in lengths of not more than 10 inches and should always reach to the bottom of the oil-container.
4. It is well to change the wick after two months' use.
5. See that the chimney of the lamp fits properly and is held sufficiently tightly so as not to fall off when the lamp is used.
6. When a new wick or chimney is required it is always advisable to take the burner to the shop that it may be properly fitted.
7. The burner should be taken to pieces and thoroughly cleaned at least once a month, and all burnt pieces of wick, dead flies, dirt, &c., should be carefully removed.
8. Never re-fill the lamp when it is alight or near a fire or other light.
9. After filling see that the burner is properly fixed on, and if there is a side filling-hole be careful to screw in the plug.
10. Before lighting remove the burnt crust of the wick.
11. Be careful not to spill oil in filling and if any is spilt on the lamp to wipe it off.
12. Before lighting see that the slit in the cone of the burner is exactly over the wick-tube, so that the flame will not touch the metal.
13. When first lit the wick should be partially turned down and then

<sup>1</sup> THE LANCET, Sept. 28th, 1901, p. 859.

gradually raised, but not so as to smoke. When the edge of the flame is orange-coloured the lamp is not burning properly and the burner should be examined.

14. Do not continue to burn the oil until it is completely exhausted. It is best to keep the lamp well filled.

15. Lamps which have no extinguisher should be put out as follows:—The wick should be turned down until there is only a small flickering flame, care being taken not to turn down so far that the wick falls into the oil-container. The small flame may be extinguished by placing a piece of flat tin or card on the top of the chimney or by blowing across the top of the chimney. Never blow down the chimney.

16. Never use a lamp which is broken or in any way out of order, or a chimney which is cracked. If any part comes loose, or is out of shape, or defective it should be taken to a lamp shop to be repaired.

17. Always place the lamp in a secure place and on a level surface, and never on a rickety table or in any position where it could be easily upset. Hanging lamps should not be put on insecure nails in the wall.

18. Table lamps should not be carried about more than is necessary, and nothing else should be carried at the same time. Heavy lamps should be carried in both hands. The greater number of lamp accidents have been caused by dropping a lamp while it was being carried.

19. Lamps should not be turned down except for the purpose of putting them out. If turned low the oil is apt to be unduly heated.

20. Should a person's clothes become ignited the flames should be smothered with a hearthrug, blanket, woollen tablecloth, or wet towel.

21. Never pour oil on a fire.

These suggestions are all excellent, but the most important recommendation of all has been omitted, namely:—

No lamp should be used in which the container is made of glass, china, or any fragile material.

Yet another point should be more brought out than it is in the circular, and that is that the wick-holder, if movable, should fit tightly either by screw or bayonet-joint.

#### INTERNATIONAL CONGRESS OF PHYSIOLOGISTS: TRIBUTE TO SIR MICHAEL FOSTER, K.C.B., M.P., SECRETARY OF THE ROYAL SOCIETY.

As we have already announced a unique tribute of international esteem was paid to Sir Michael Foster by the members of the Fifth International Congress of Physiologists assembled at Turin in unanimously electing him to the office of Honorary Perpetual President of the Congress. In commemoration of this event a plaque bearing a suitable inscription was presented to Sir Michael Foster on Sept. 18th, at a special meeting of the Congress. Sir Michael Foster was one of the most active of the original founders of the Congress and it is due mainly to his energy that another important international association, the International Association of Academies, which has taken over part of the work of the Physiological Congress, has been established. The tribute is therefore a well-merited one. In connexion with the Congress at Turin the definite establishment of two other important international institutions was announced—one for the control and unification of physiological and clinical recording instruments and the other for the observance of the physiological and therapeutical effects of life at high altitudes. The latter has been erected on the summit of Monte Rosa with the aid of funds supplied by the Dowager Queen Margherita of Italy. The former has been granted separate housing by the Municipality of Paris in the Parc au Princes in that city. Both institutions will be placed under the control of the International Association of Academies. At the concluding general meeting of the Congress held on Saturday, Sept. 21st, it was unanimously resolved that the next Congress should be held at Brussels in 1904, under the Presidency of Professor Heger.

We commend to the notice of our readers an address delivered by General Ian Hamilton to the students of St. Thomas's Hospital Medical School on Wednesday last, on the occasion of the annual prize-giving. If the re-constituted Royal Army Medical Corps is greeted in such a spirit by other distinguished combatant officers its popularity will be much increased. An abstract of the address will be found on p. 933.

MR. WILLIAM WALDORF ASTOR has sent to the chairman of the National Society for the Prevention of Cruelty to

Children a cheque for £10,000, which sum is to form the nucleus of a fund for the acquisition of premises adequate for the transaction of the society's business.

THE Gresham Lectures in Medicine will be delivered in Gresham College, Basinghall-street, London, E.C., on Oct. 8th, 9th, 10th, and 11th, at six o'clock, by Dr. Symes Thompson, Gresham Professor of Medicine, who has taken for his subject "The Tuberculosis Congress."

WE have received the report of Mr. Brodrick's Committee upon the Army and Indian Nursing Service. The *personnel* of the Committee is the same as that which has had the Army Medical Service under consideration.

THE usual demonstrations of cases at the National Hospital for the Paralysed and Epileptic, which had been discontinued owing to the recent difficulties, will be resumed on Tuesday, Oct. 8th, at 3.30.

THE new buildings of the Post-Graduate College at the West London Hospital will be opened on Oct. 14th at 5 P.M., when an address will be delivered by Sir William Mac Cormac.

#### REORGANISATION OF THE ARMY MEDICAL SERVICES.

WE have received for publication the Report of Mr. Brodrick's Committee appointed to consider the Reorganisation of the Army Medical Services. The Committee consisted of the following members:—Mr. Brodrick, M.P. (chairman), Colonel Sir Edward Ward, K.C.B., Permanent Under-Secretary for War (vice-chairman), Major-General Sir G. de C. Morton, Colonel Sir James Willcocks, Sir Frederick Treves, Sir William Thomson, Surgeon-General Hooper, I.M.S., Lieutenant-Colonel A. Keogh, R.A.M.C., Mr. G. H. Makins, Mr. A. D. Fripp, Dr. H. Tooth, Professor A. Ogston, and Dr. E. C. Perry, with Major H. E. R. James, R.A.M.C., as secretary. The report of the Committee is as follows:—

#### SCHEME FOR THE REORGANISATION OF THE ARMY MEDICAL SERVICES.

##### ADVISORY BOARD.

1. The Royal Army Medical Corps shall be under the supervision of a Board to be termed the Advisory Board for Army Medical Services and constituted as follows:—

The Director-General, A.M.S., Chairman.

The Deputy-Director-General, A.M.S., Vice-Chairman.

One officer, Royal Army Medical Corps, with special knowledge of sanitation.

One officer, Royal Army Medical Corps, with special knowledge of tropical diseases.

Two civilian physicians appointed by the Crown on the recommendation of the Secretary of State.

Two civilian surgeons appointed by the Crown on the recommendation of the Secretary of State.

One representative of the War Office appointed by the Secretary of State.

One representative of the India Office appointed by the Secretary of State for India.

The Matron-in-Chief, Queen Alexandra's Imperial Military Nursing Service (for nursing service only).

2. To be eligible for appointment upon the Advisory Board a civilian physician or surgeon shall be required to hold or to have recently held a post on the acting staff of a leading civil hospital in England, Wales, Scotland, or Ireland, and to be not more than 55 years of age upon first appointment.

3. A civilian physician or surgeon upon the Advisory Board shall hold office for a period of three years, renewable upon expiration of the term of his appointment, but subject to the proviso that he shall vacate his seat on the Board upon

attaining the age of 60 years. He shall receive an honorarium of £200 per annum in addition to his out-of-pocket expenses for duties performed beyond a radius of four miles from Charing Cross.

4. The Advisory Board shall usually meet at fortnightly intervals, and the necessary quorum for the transaction of business shall be the Chairman (or in his absence the Vice-Chairman) and two other members of the Board, of whom one must be a civilian. The Chairman (or in his absence the Vice-Chairman) shall have the right to vote, and, in case of an equality of votes, shall have a casting vote.

5. The Advisory Board shall report to the Secretary of State upon all matters concerned with medicine, surgery, sanitation, and epidemic diseases as they affect the military services.

6. The Board shall advise the Secretary of State upon the adequate provision of hospitals and upon the equipment of the same in full detail; upon the supply of drugs, appliances, diets, and medical comforts to the patients; and generally upon whatever concerns the well-being of the sick and wounded.

7. The Board shall prepare and submit to the Secretary of State a scheme for the expansion of the Service to meet the needs of war or serious epidemics, such scheme dealing with questions of ambulance and transport, the equipment of all medical units at the base and front and on the lines of communication, the supply of drugs and medical comforts, the employment in the Service of civilian surgeons, nurses, and orderlies, and the utilisation of all voluntary effort for the relief of the sick and wounded.

8. The Board shall have submitted to it, and shall report to the Secretary of State upon, all plans for new hospitals and upon standard plans for barracks and standing camps.

9. It shall be the duty of the Board to draw up a list of civil hospitals recognised as places of study for members of the Royal Army Medical Corps.

10. The Board shall also draw up a list of hospitals and nurse-training schools recognised for the purposes of the Queen Alexandra's Imperial Military Nursing Service.

11. The Board shall arrange, so far as practicable, for the annual inspection of each of the military hospitals by a Sub-Committee consisting of at least one military and one civilian member of the Board, such inspection to be usually made without notice.

12. This Sub-Committee shall ascertain and report to the Board whether the treatment of patients and the equipment of hospitals inspected be in accordance with modern medical and surgical requirements.

13. The Board may, with the permission of the Secretary of State, detail specially qualified officers of the Royal Army Medical Corps or others to visit and report upon the army medical services of foreign countries.

14. The promotion of officers or their retention in the Service will be referred to the Board for consideration before submission by the Director-General to the Commander-in-Chief.

15. The Board shall supervise the admission of candidates to the Royal Army Medical Corps, and shall arrange for the examination of officers for promotion, appointing examiners and recommending to the Secretary of State the amount of their remuneration, regard being had as heretofore to the English, Welsh, Scotch, and Irish medical schools. Except as specified in paragraph 25, examinations shall be held every six months at dates to be fixed by the Advisory Board. Examiners shall be appointed annually by the Advisory Board, but no examiner shall serve continuously for a longer period than four years. A member of the Advisory Board shall not be appointed examiner.

16. The Board shall exercise a general control over the nursing service, and, in consultation with the Nursing Board, shall submit to the Secretary of State a scheme to develop the training of orderlies as attendants upon the sick and wounded.

#### DIRECTOR-GENERAL.

17. The Director-General shall be appointed by the Secretary of State on the recommendation of the Commander-in-Chief, acting with the advice of the Advisory Board, and shall hold office for five years.

18. The Director-General shall be responsible for the administration of the Army Medical Service, the Militia Medical Staff Corps, the Militia Reserve trained in medical duties, and the Volunteer Medical Staff Corps. He shall be

responsible for the distribution, promotion, discipline, and general organisation of these services.

19. After reference to the Advisory Board as defined in paragraph 14, the Director-General shall bring forward to the Commander-in-Chief the names of officers whom he may judge worthy of promotion.

20. The Director-General, in concert with the Advisory Board, shall draw up a scheme for the due provision of medical aid for the Auxiliary Forces, Militia, Yeomanry, and Volunteers.

#### CANDIDATE AND LIEUTENANT ON PROBATION.

21. A candidate for admission to the Royal Army Medical Corps shall be a British subject of unmixed European blood, not more than 28 years of age, and shall possess a registrable qualification to practise. He shall produce a certificate of birth or other satisfactory proof of age, and shall furnish to the Advisory Board such evidence as may be required regarding character, conduct, professional ability, and fitness to hold a commission in the corps. Special importance shall be attached to a confidential report to be requested by the Board from the dean or other authority of the school in which the candidate has completed his course as a medical student.

22. Subject to such arrangements as may hereafter be made, opportunities will be given for civilian surgeons over age, who have served with troops in the field, to enter the corps. Special marks, on a scale to be fixed by the Advisory Board, shall be granted to candidates who have performed medical duties with troops on active service.

23. A candidate, having fulfilled the above requirements, shall be directed to appear before the Advisory Board, who will decide whether he may be allowed to compete for a commission in His Majesty's Army.

24. After having been medically examined the candidate shall be submitted to a clinical and practical examination in medicine and surgery, the scope of which shall be defined by the Advisory Board.

25. Having gained a place in this Entrance Examination, the successful candidate shall be appointed Lieutenant on probation, and shall proceed to Netley (until other arrangements have been made) for a two-months' course of instruction in hygiene and bacteriology, after which he shall be examined in these subjects. He will then proceed to Aldershot, where he will undergo a three-months' course of instruction in the following subjects:—

Stretcher and ambulance drill.

Interior economy.

Military law and hospital management.

On the completion of the course he shall be examined in these subjects. The marks gained at both these examinations (provided they are not less than the 50 per cent. requisite to qualify), added to those at the entrance examination, shall decide his position on the seniority list of the corps, and he will thereupon be confirmed in his appointment as Lieutenant. The mark ratio of each of these minor examinations to the entrance examination shall be as 1 to 8.

26. A Lieutenant on probation who fails to obtain the qualifying percentage of marks in either of these minor examinations shall be allowed a second trial at the termination of six months from entrance to the Service, and should he qualify will be placed at the bottom of the list. If, however, he should again fail in either examination, his appointment will not be confirmed, and he will leave the Service.

27. Should a candidate pass the entrance examination, the Royal Army Medical Corps whilst holding a resident appointment in a recognised civil hospital, or be appointed thereto at such a date as will permit him to take up his duties immediately after he has passed the entrance examination for the Royal Army Medical Corps, he shall be seconded for the period of such appointment not exceeding one year, receiving, however, during such period no pay from army funds, but counting his service towards pension or gratuity.

28. A Lieutenant, on completion of his course of instruction, will be attached for duty to a battalion, regiment, or other unit, but while thus attached will also be detailed for duty in a station hospital; but this provision shall not entitle any unit to claim that a medical officer should be attached thereto.

29. At the end of three years from the confirmation of his appointment as Lieutenant he will be permitted to retire,

or if, in the opinion of the Advisory Board (based on the reports received from his principal medical officer and the commanding officer of the unit to which he has been attached), his service has been satisfactory, he will be allowed by the Secretary of State to adopt one of the following courses:—

(a.) To continue in the Service.

(b.) To engage for a period of seven years in the Reserve of Officers, receiving a sum of £25 per annum while so serving. An officer who has been in the reserve for a period of not less than one year or more than three years may be permitted by the Secretary of State on the report of the Advisory Board to return to the active list, and if replaced on the active list he shall be allowed to count one-third of his service in the reserve towards promotion, pension, or gratuity.

30. Should the officer elect to continue in the Service he shall be attached for a period of six months to a recognised hospital in a centre where he has opportunities of gaining further professional knowledge by attendance at a course or courses of instruction in a civil hospital, or otherwise, as may be approved by the Advisory Board.

31. At the end of six months of such instruction he shall present himself for examination in medicine; surgery; hygiene and sanitation; and bacteriology and tropical diseases. In this examination the relative value of the subjects expressed in marks shall be as follows:—

Medicine, 100; surgery, 100; hygiene and sanitation, 70; bacteriology and tropical diseases, 50.

The percentage of the total number of marks necessary to obtain distinction shall be as follows:—

Special certificate of excellence	...	85 per cent.
1st class	...	80 "
2nd "	...	70 "
3rd "	...	60 "

The qualifying mark in each subject shall be 40 per cent.

32. On the results of this examination an acceleration of promotion may be granted at the discretion of the Secretary of State, provided that the officer's conduct has been satisfactory, in accordance with the following scale:—

Class in examination.	Acceleration of promotion.
Special certificate of excellence	18 months.
1st class	12 "
2nd "	6 "
3rd "	3 "

33. An officer who does not reach the qualifying mark in each subject shall be considered as having failed to pass the examination and shall be placed on a supernumerary list for a period not exceeding six months, when he shall be required again to present himself for examination in all subjects, and if he fail a second time he shall be compulsorily retired. Service on the supernumerary list shall not count for pension, increase of pay, or promotion.

#### CAPTAIN.

34. When an officer has passed the examination specified in paragraph 31 he shall be promoted Captain, and shall undergo a short course of instruction in field hospital work, bearer company drill, or allied subjects approved by the Advisory Board, and on the conclusion of the course he shall be posted to such station and duty as the Director-General may order.

35. On the conclusion of six years' service as Captain, subject to such acceleration as he may have obtained under paragraph 32, an officer shall be allowed by the Secretary of State to adopt one of the following courses:—

(a.) To retire with a gratuity of £1000.

(b.) To continue in the Service.

36. Should he elect to continue in the Service, an officer, between his ninth and twelfth year of service (subject to such acceleration as he may have obtained under paragraph 32), shall be attached to a selected hospital at one of the military centres, so as to enable him to attend the practice of a recognised civil hospital for a period of six months, at the end of which period he will be required to present himself for examination in the following subjects:—

Medicine; surgery; hygiene and sanitation; bacteriology and tropical diseases; military law, administration and interior economy; and one special subject

from the subjoined list of optional subjects, to which additions may from time to time be made by the Advisory Board:—

Bacteriology, including the preparation of anti-toxins.

Dental surgery.

Dermatology.

Fevers.

Laryngology.

Midwifery and gynaecology.

Operative surgery (advanced).

Ophthalmology.

Otology.

Pædiatrics.

Psychological medicine.

Skiagraphy.

37. In this examination the relative value of the subjects expressed in marks shall be as follows:—

Medicine, 100; surgery, 100; hygiene and sanitation, 100; bacteriology and tropical diseases, 100; military law, administration and interior economy, 100; special subject, 100.

The percentage of the total number of marks necessary to obtain distinction shall be as follows:—

Special certificate of excellence	...	85 per cent.
1st class	...	80 "
2nd "	...	70 "
3rd "	...	60 "

The qualifying mark in each subject shall be 40 per cent.

38. On the results of this examination an acceleration of promotion may be granted at the discretion of the Secretary of State, provided that the officer's conduct has been satisfactory, in accordance with the following scale:—

Class in examination.	Acceleration of promotion.
Special certificate	18 months.
1st class	12 "
2nd "	6 "
3rd "	3 "

39. An officer who does not reach the qualifying mark in each subject shall be considered as having failed to pass the examination, and shall be placed on a supernumerary list for a period not exceeding six months, when he shall be required again to present himself for examination in all subjects, and if he fail a second time he shall be compulsorily retired. Service on the supernumerary list shall not count for pension, increase of pay, or promotion.

40. An officer who in the opinion of the Advisory Board has been prevented by the exigencies of the Service, or by other very special circumstances, from presenting himself for examination as required in paragraphs 31 and 36, may be provisionally promoted, subject to his passing the prescribed examination at the first available opportunity.

41. In order to encourage the study of the special subjects enumerated in paragraph 36, appointments shall be made in each army corps and in such other places at home and abroad as may be approved of by the Secretary of State, of officers below the rank of Lieutenant-Colonel who shall receive specialist pay according to the rate given in the Appendix. To be qualified for appointment as specialist, an officer must have gained at least 70 per cent. of the marks in the special subject taken in the examination mentioned in paragraph 36. Specialists may also be appointed in Public Health, if they have first qualified by obtaining a diploma recognised for registration by the General Medical Council.

No officer shall hold more than one specialist appointment at the same time.

42. In case of an officer desiring to engage in advanced professional study, it shall be open to the Advisory Board to recommend that special leave be granted him for a period of six months.

#### MAJOR.

43. An officer, having completed 12 years' service (subject to such acceleration as he may have obtained under paragraphs 32 and 38), and having passed the necessary examination, shall be promoted Major, and shall continue to serve in that rank under the following conditions:—

(a.) After three years' service from the date of his promotion to the rank of Major, he shall be granted a higher rate of pay (see Appendix).

(b.) At the conclusion of three years from the date of his advancement to the higher grade (making six years in the rank), he shall, if his service has been satisfactory, be allowed by the Secretary of State to adopt one of the following alternatives:—

(i.) To retire on a gratuity of £2500 (see Appendix).

(ii.) To continue in the Service.

44. Should he elect to continue in the Service, he shall, before he has completed 20 years' service (subject to such acceleration as he may have obtained under paragraphs 32 and 38), be granted three months' study leave, and at the end of that time be required to undergo a qualifying examination for promotion to the rank of Lieutenant-Colonel, in the following subjects:—

- (1.) Hospital organisation, administration, and equipment in peace and war, including the disposal of the sick and wounded.
- (2.) Organisation, administration, and equipment in war of all medical units in the field and on the lines of communication.
- (3.) The sanitation of towns, camps, troop-transports, and all places likely to be occupied by troops in peace and war.
- (4.) Epidemiology and management of epidemics, and the relations of civil law as regards infectious diseases.
- (5.) The medical history of important modern campaigns.
- (6.) The administration, command, and discipline of the Royal Army Medical Corps, and of other persons who may come under the jurisdiction of an officer of the corps.
- (7.) The duties of all ranks in the Royal Army Medical Corps.
- (8.) Recruiting and invaliding, including a knowledge of civil law as it affects lunatics in the Service.
- (9.) The relations of the medical to all other branches of the Army as defined by the various codes of regulations in force.
- (10.) The Army Medical Services of other Powers.

45. Should an officer fail to obtain 50 per cent. of the total number of marks, he will be allowed, after an interval of six months and before he has completed his twentieth year of actual service, to present himself again for examination. Should he fail a second time, he will be compulsorily retired on a gratuity of £2500, or he may, by special permission of the Secretary of State, complete 20 years' service and then retire on a pension.

46. Promotion to the rank of Lieutenant-Colonel will be by selection from among those officers who have passed the qualifying examination, and who have completed 20 years' service, subject to such acceleration as he may have obtained under paragraphs 32 and 38. If not selected for promotion within 12 months from the completion of 20 years' actual service, an officer will be permitted to remain on the pay of a Major until he completes 25 years' service, subject to acceleration, when he will be compulsorily retired on the pension of his rank (see Article 527, Royal Warrant).

#### HIGHER RANKS, HOSPITALS, &c.

47. During his service as Lieutenant-Colonel an officer may be selected for a higher rate of pay under Article 362, Royal Warrant for Pay and Promotion, which rate he will retain until promotion to the rank of Colonel.

48. The promotion to the rank of Colonel and Surgeon-General shall be by selection. Service in India shall not be necessary for promotion to either rank.

49. Medical officers shall be eligible for brevet promotion in the Royal Army Medical Corps in the same manner as officers in the other branches of the Service; and such promotion may be given either for distinguished service in the field or for distinguished service of an exceptional nature other than in the field.

50. Junior medical officers shall be gazetted directly to the regiments of the Household Brigade, and shall not be attached to them from the Royal Army Medical Corps as at present.

51. By special authority of the Secretary of State medical officers of the Household Brigade may be appointed Colonels in the Royal Army Medical Corps if they have complied with the conditions laid down in Article 362, Royal Warrant for Pay and Promotion, or as a reward for exceptional merit on active service.

52. When an officer is in charge of a hospital he shall receive charge pay at the rate specified in the Appendix.

53. The appointment to the charge of certain selected station hospitals, to be hereafter specified by the Advisory Board, shall be for a term of not less than three years.

54. With the exception of officers attached to units, appointments to a district shall, unless broken by a tour of foreign service, be for a term of two years.

55. Should it be necessary to move an officer from his station for other than temporary duty at an earlier date, a report of the circumstances shall be forwarded by the principal medical officer of the army corps to the Director-General.

56. The principal medical officer in each army corps and in each district shall be the staff officer of the general officer commanding for all medical and sanitary services, and shall be responsible to him for the administration of all hospitals and medical stores.

57. The principal medical officer shall deal with all matters in his district, and shall only refer to the Advisory Board in cases of serious doubt or difficulty.

58. Every army corps shall have a completely equipped bearer company and field hospital and a proportion of other medical field units at its headquarters, in order that the officers and men of the Royal Army Medical Corps may receive instruction and gain practical experience in the performance of field duties.

59. With the view of reducing the number of slight cases of illness in hospital, and thus providing accommodation for those of a serious nature, convalescent homes shall be established in each district to which soldiers recovering from severe illness may be sent. These homes, which are intended for men who are so far recovered as to be able to dispense with the services of nurses, shall be visited daily by a medical officer.

60. Medical officers in charge of units shall be instructed to retain in barracks cases of injury or illness of a trivial character, which are likely only to interfere for a few days with the soldier's performance of his duties.

61. For the reception of such cases a barrack-room shall be set aside, when available, in which they will be attended by the medical officer in charge of the unit. The medical officer will, however, as far as possible, treat light cases of illness as out-patients.

62. In small stations where no military hospitals are available arrangements may be made with the authorities of the local civil hospital for the admission thereto of cases requiring treatment as in-patients.

63. With the view of relieving the pressure of clerical work now experienced by the officers and men of the Royal Army Medical Corps, the Secretary of State has directed that steps shall be taken to simplify the returns rendered by medical officers and the forms of accounts used in hospitals.

64. Consulting physicians and surgeons from the acting staff of recognised civil hospitals shall be appointed by the Advisory Board to attend when required at military hospitals at such times as may be desired by the medical officers in charge. Members of the Advisory Board shall not be eligible for appointment as consulting physicians or surgeons.

65. In order that opportunities for instruction and special advice may be obtained, serious cases will be concentrated whenever practicable in the larger military hospitals—e.g., Woolwich, Millbank.

66. The Committee is strongly of opinion that the establishment of a military hospital and medical staff college for the training of officers of the Royal Army Medical Corps would very materially conduce to the efficiency of army medical service. It recommends that immediate steps be taken by the Advisory Board to present a detailed scheme for the establishment of such a hospital and staff college for the consideration of the Secretary of State.

H. E. R. JAMES, Major, R.A.M.C., Secretary.

\* Subject to remarks printed below.

## Exceptions by Sir William Thomson, C.B.—

1. Having regard to the important functions and powers of the civilian members of the Advisory Board, as set out in the report, I am strongly of opinion that it should be composed of representatives of the medical schools in the several divisions of the kingdom.

The sum proposed to be paid would practically exclude other than London teachers, although 70 per cent. of the medical officers come from schools outside England.

2. It is inadvisable to fix an age limit for civilians on appointment.

This is not done in the case of the other representatives.

The Secretary of State for War can always protect himself in this regard when making selections.

WILLIAM THOMSON.

## Exceptions by Professor A. Ogston—

I consider that the scheme falls short of what is requisite among other things in the following matters, viz. :—

1. It does not provide for the formation of a sanitary corps, consisting of officers specially charged with the duty of carrying out proper sanitary measures in peace and war, and a staff of men trained to ensure the requisite measures being carried into effect.
2. It does not provide such study leave as the advancing state of medical science now demands, and is likely in the future to demand even more, nor such liberal privileges in this direction as have been found necessary in the armies of other great European Powers.
3. It makes no provision for placing at the disposal of the many medical officers serving in remote and isolated stations abroad such information as will enable them to familiarise themselves with the advances of medical science, and as is called for in the interests of those who are placed under their care.
4. It fails to provide for medical officers being trained by attendance upon civilian patients in all the branches of their profession, so that they may become equally skilful with their civilian brethren and may avoid the narrowing influences which act so injuriously upon medical officers who have to deal only with the treatment of soldiers and military officials.

ALEX. OGSTON.

## APPENDIX.

## PROPOSED RATES OF PAY, &amp;C., FOR MEDICAL OFFICERS.

	Pay per annum.	Allowances, servants, lodging, fuel, and light.	Total.
	£ s. d.	£ s. d.	£ s. d.
Lieutenant on Probation and Lieutenant ... ..	250 0 0	73 10 0	323 10 0
Captain, i.e., after three years' service ... ..	287 0 0	92 15 2	379 15 2
Captain, after seven years' total service ... ..	307 4 10	92 15 2	400 0 0
Captain, after 10 years' total service ... ..	385 0 0	92 15 2	477 15 2
Major, i.e., after 12 years' total service ... ..	430 0 0	157 12 10	587 12 10
Major, after three years' service as such ... ..	475 0 0	157 12 10	632 12 10
Lieutenant-Colonel, i.e., after 20 years' service ... ..	547 0 0	166 15 4	713 15 4
Lieutenant-Colonel, selected under paragraph 362 of the Royal Warrant (establishment of 50) ... ..	638 0 0	166 15 4	804 15 4
Colonel ... ..	730 0 0	233 10 10	963 10 10
Surgeon-General ... ..	Consolidated		1500 0 0
Director-General ... ..	—		2000 0 0

The pay of officers of the Royal Army Medical Corps below the rank of Major while serving in India shall be

increased so as to bear the same ratio to the above rates for non-Indian service as at present exists.

## CHARGE PAY (see paragraph 52).

	s.	d.
Hospitals of 300 beds or more ... ..	10	0 per diem.
" 200 " ... ..	7	6 "
" 100 " ... ..	5	0 "
" 50 " ... ..	2	6 "

## SPECIALIST PAY (see paragraph 41).

In public health and in any subject mentioned in paragraph 36, 2s. 6d. per diem.

## RETIRED PAY AND GRATUITIES.

As already existing, with the following exceptions (see paragraphs 29 and 35):—

Pay on the reserve, £25 per annum.

Gratuity after nine years' service, £1000; £2500 after 18 years' service.

## THE NEW SCHEME FOR THE ROYAL ARMY MEDICAL CORPS.

MAJOR-GENERAL SIR IAN HAMILTON, K.C.B., speaking at the distribution of prizes at St. Thomas's Hospital on Oct. 2nd, said that war was a great test of character. Amidst the intensely artificial surroundings of modern civilisation anyone might live with a man or woman for years and not find out what he or she really was. How could anyone tell if even his nearest friend was greedy or self-denying when there was no real lack of provender whereby to put the question to the test? During a siege he had seen an insufficiency of food passed round six men and when the plate came to the fifth man there was already nothing on it. Soldiers who had seen a certain amount of service recognised the genuine article amongst those who had served with them at such periods, and it was because he was one of those who had seen doctors in the field that he was there that day.

What he principally wished to speak about was with regard to the new scheme for the reorganisation of the Royal Army Medical Corps. Since the old days of regimental doctors the Royal Army Medical Corps had survived, but only just survived, innumerable vicissitudes. Through all of them the heart of the organisation had beat sound, but difficulties and unpleasantnesses had, on the whole, so predominated that the men who had risked all and entered the service had shown by that action alone that they possessed good hearts and sanguine dispositions. It had been objected, perhaps not without reason, by that enthusiastic military reforming organ the *Morning Post*, that the public had been favoured with no preliminary remarks setting forth the objects which the Committee had in view. He would now state these objects, not authoritatively, but to the best of his belief. The objects were:—

1. To retain as much of the existing system as was good and to substitute for that which was bad certain fundamental principles upon which the genius of civil and medical administration could construct.
2. To offer to the medical profession itself the power to produce such a system of medical aid in peace and war as would bring to the soldier all the benefits which modern science provided for his civil brother.
3. To offer to the military physician, the military surgeon, and the military sanitarian the fullest opportunities of perfecting themselves in their various crafts.
4. Generally the revivification of a corps which in matters purely professional had fallen upon evil times.

The scheme should be read well between its lines and, recollecting that it was but a framework, its scientific possibilities in sympathetic hands would be understood. There would come the rub—the hands must be sympathetic and kindly, and not only the hands of the War Office but those of the Government of India. There was something not in this scheme which could not, indeed, find a place in any scheme. It was something which characterised the medical profession perhaps above all other professions. The highest ambition of the scientific man was to be able to do something for science, and he thought that the scheme afforded opportunities of adding to the store of knowledge now being

accumulated. The officer of the Royal Army Medical Corps would be able in the future to take that place in the scientific world which was open to all comers who were worthy of it. He would have to begin at the beginning, which in England now, as in China, invariably meant an examination. Examinations being the national craze of the moment, it was really too much to expect that the scheme should not have a succession of examinations as one of its features. He detested the present style of examination as much as any student; all he would say for the scheme in this connexion was that the endeavour seemed to have been to make these tests as little harmful as possible to the brain, character, and physique of the victims. Instead of the present extensive entrance examination in the medical and kindred sciences there would be in the future clinical and practical examinations designed to select the best all-round practical men, men who had profited most from their ward and laboratory work. Such an examination would, it was hoped, encourage the experienced and advanced student and debar the inexperienced, merely bookish, person possessed of a crammed superficial knowledge which evaporated in the twinkling of an eye, "like a snowflake on a river, one moment seen, then lost for ever," the moment being the period of the examination, when it dazzled with its transient gleam the spectacled orbs of the crabbed examiner. As military secretary he was supposed to be primarily responsible for the education of the young combatant officers, and he would be proud if at the close of his tenure he could say that he had done something to approximate the class of examination undergone by them to that now proposed for the medical department.

Once the examination had been negotiated there would be higher pay to start with and higher pay all along the line to look forward to. Not only, indeed, was higher pay to be granted all round, but charge pay would be granted for charge of hospitals, it having been little short of a scandal that under what might now be called the late system a young officer should have had to spend money out of his own pocket if he wished to have his hospital arrangements properly up to the mark. All this would now be put right by the handsome charge allowance which would be granted. It would be observed that there would be examinations for each step in rank on the same principle as other branches of the service. The examination *plus* the preliminary courses would be of such a practical nature that opportunities for distinction by capable, as distinguished from merely clever, men would be obtainable. These distinctions were not empty ones; they carried with them the solid advantages of special promotion on a fixed scale. It would be noted also that advancement without examination or for war service was also provided for. The idea was that responsibility and reward should hereafter be given in commensurate proportion with capability and not merely upon seniority. The Royal Army Medical Corps had persistently asked for study leave and had not got it; they had asked for bread and had been offered red facings. The authorities had now repented and in their repentance meant to go one better. They were going to make their officers take study leave *volens volens*, only they were not going to let them study the female form divine in ball-rooms, or the grouse disease in Aberdeen, or broken arms and legs with the Ward Union of Dublin. But they would concentrate them at centres where their studies would be supervised and directed. Thus not only would the young officers benefit by getting real instead of sham study, but Lord Roberts, through his staff, would get to know his men and their qualifications, which might possibly tend to prevent for the future a bacteriologist being detailed to cut off arms and legs and a brilliant surgeon having to investigate the intermarriages and banquets of bacilli.

Finally, in this connexion he knew they were glad for the sake of the army and its health that the military hospitals were to be in future equipped in every way so as to rival the best hospitals in the world; also that the scientific apparatus so necessary for successful treatment of disease would be liberally provided. All these were vast changes, some of them fundamental in their character, but a greater one still was perhaps to be found in the fact that for the first time eminent members of the civil medical profession would be given a voice in the direction of the fortunes and conduct of the Royal Army Medical Corps. The wisdom of this might be questioned by the timid, but he himself held that it was far more important for the corps to stand shoulder-to-shoulder and arm-in-arm with their civilian brethren than it was for them to be picked military

officials. He hoped he had said nothing to deter any of those present from coming to the army. Their representatives had many warm friends in the combatant ranks, friends who got more numerous and stronger as the war gave more and more prominence to the splendid devotion of the Royal Army Medical Corps.

## THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

### THE ELECTION OF DIRECT REPRESENTATIVES.

THE following is the text of Dr. GLOVER's election address:—

#### FELLOW PRACTITIONERS OF ENGLAND AND WALES,—

In offering myself again for re-election as one of your Direct Representatives on the General Medical Council I have two duties to discharge. I have to thank you, as I do most heartily, for a long period of confidence and support on your part, shown in three elections. And I have to explain the principles on which I have endeavoured to act as your Representative on the General Council of Medical Education and Registration, and to which I shall adhere in the event of your again electing me. The recent address which I delivered at Cheltenham and my action for years in the Council make it unnecessary for me to do more than very briefly indicate my views.

Firstly, I have endeavoured to the best of my ability, in respect of medical education, to make it, above all things, clinical and practical, basing it on as high a standard of preliminary education as the state of our general education will permit.

Secondly, I have laboured to maintain the purity of the Register, and while not lightly using the disciplinary power of the Council have not hesitated to apply it in the case of those who knowingly and persistently violate those traditions of the profession which are necessary for its honour and for the protection of the public.

Thirdly, in regard to legislation to regulate the work of midwives, I have kept in view the following objects:—

- (a) Stopping the practice of "Sarah Gamps"—as we stop the sale of poisons.
- (b) Limiting the practice of midwives to simple cases and placing them under strict compulsion to call for the assistance of regular medical practitioners on the occurrence of any irregularity or abnormality in mother or child.
- (c) Providing in respect of the training and certification of the work of midwives a board to do with the sanction of law what is now done without legal authority by the Obstetrical Society of London and by other more or less irregular bodies.
- (d) As midwives are not medical practitioners and can only safely work under the supervision of such practitioners I can only support legislation for recognising them on condition that it secures the above objects by making the Midwives Board to consist chiefly of medical men and subjecting its regulations to the approval of the General Medical Council.

Fourthly, I have consistently supported motions for an increase in the number of Direct Representatives in the Council, and I should support any reasonable proposals for reducing the size of the Council.

Fifthly, the Medical Council consists predominantly of the representatives of 20 or more qualifying bodies, these bodies having their own functions and responsibilities. It is very creditable to the Council and the bodies that so little friction has hitherto arisen between them and it. At present the best friends of medical education see with concern and regret a sharp difference between the Royal Colleges of England and the Council. I shall only say here that while ready to support the just claims of the Council to the loyal support of the individual bodies, I am in favour of avoiding any course which necessitates a reference to the Privy Council, which by law has the last word in any dispute between the Medical Council and the individual examining bodies, believing it to be in the interest of the Council and of the profession to settle differences without such reference.

Sixthly, I am strongly in favour of the formation of a

Conciliation Board to remove friction between the medical profession and the friendly societies, to improve the position of the medical officers, and gradually to raise the conception of the value of medical service to the working-classes. As acting chairman of a committee on these subjects I have been much impressed with the disposition of the leaders of the friendly societies to meet the just complaints of the medical profession, and I may add that the same impression has been made on my colleagues in the Medical Council and on the Committee of the Council of the British Medical Association. It will be a misfortune if the tendency in some quarters to disparage this movement should receive any sanction at the coming election of Direct Representatives.

Seventhly, the finances of the Council require the consideration of its members, the expenditure of late years having largely exceeded the income. Serious proposals have been made for raising a huge income for the Council by a yearly registration fee. I am strongly opposed to such a suggestion and believe it to be unnecessary. The difficulty, in my judgment, is to be met rather by reducing the expenditure of the Council in obvious ways than by exacting what would be an annual tax from the profession. Medical politics may seem unimportant to many practitioners. The large abstention of voters in past elections of Direct Representatives gives some colour to that impression. But medical politics deeply affect the welfare and reputation of the profession and are entitled to the consideration of all who are in any way responsible for the composition of the Medical Council.

Such are the views on which I have acted as the Direct Representative of the practitioners of England and Wales on the General Medical Council. Though conscious of many errors and defects I appeal with some confidence to the broad and generous judgment of the profession, and remain your obedient servant,

JAMES GREY GLOVER, M.D.

25, Highbury-place, N.

## FEMALE INSPECTORS OF WORKSHOPS.

IN a report for the nine weeks ending Sept. 14th presented to the Sanitary Committee Dr. William Collingridge, medical officer of health of the City of London, states that a house-to-house inspection of workshops in the City "shows that women only were employed in 39 per cent. of the workshops, while no less than 72 per cent. of the total number of workers employed in these houses were women." It is obvious, he says, that there are many questions in connexion with the sanitary surroundings of female workers in factories that can only be properly investigated by one of their own sex; "moreover, the Legislature has of late years insisted upon the observance of many regulations in places where women are engaged which men are ill-fitted to conveniently control." Dr. Collingridge therefore recommends that the Sanitary Committee should immediately appoint at least one female inspector whose duties should be entirely separate from those of the male officers and strictly confined to visiting those establishments where women are employed. Any question involving structural alterations or drainage work would be dealt with by the sanitary inspector of the district. A woman charged with these duties should hold a statutory qualification as a sanitary inspector and should be duly appointed as such under the Public Health (London) Act, 1891, for the purpose of acquiring the right of entry and power to serve preliminary notices and sign certificates. He remarks incidentally that such officers have been appointed by the metropolitan boroughs of Kensington, St. Pancras, Islington, Hackney, Southwark (St. George the Martyr), and Battersea, as well as by the provincial towns of Nottingham, Salford, Birmingham, Liverpool, and Sheffield. In continuation of this subject Dr. Collingridge mentions that last June a workshop where three women were employed was found to be without separate closet accommodation. When served with a notice in accordance with the Act the owner dismissed the only actual woman worker, but questioned the right to compel the provision of accommodation for the two other women who were not constantly employed upon the premises. The Home Office inspector, however, contends that separate accommodation should still be provided, relying upon the case of Bennet

v. Harding, in which it was held that stables with a stable-yard were "a work-place" within the meaning of Section 38 of the Public Health (London) Act, 1891, and that the cab-drivers were "in attendance" there, although they were there as customers, and that sanitary conveniences must be provided for them. The owner of the workshop where the three women were employed now states that his landlord will not provide for the necessary arrangements being made and that he may be compelled to dismiss both his clerk and collector in order that the law may not be infringed. Another case of a similar character has occurred in the same sanitary district; the landlords said that the necessary alterations would be too expensive and the tenants were therefore compelled to discharge two female employées.

## THE FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

HELD AT TURIN, SEPT. 17TH-21ST, 1901.

THE following are notes of some of the communications made to the above Congress:—

### *Motor Areas of the Anthropoid Brain.*

Professor C. S. SHERRINGTON, F.R.S., and Dr. A. S. GRÜNBAUM described experiments performed on the brains of 10 chimpanzees, one orang, and one gorilla, which yielded results differing in several important points from those hitherto accepted. The brains were excited by a unipolar method, one electrode being placed round the animal's fore limb and the other applied to the area under observation. The same strength of current was able to provoke movement in the brains of the cat, rhesus, and chimpanzee. They therefore concluded that no stronger current was required for the higher brain than for the lower, contrary to what had been supposed by Horsley and Beever in the case of the orang. No movements whatever were obtainable from excitation of the posterior central (ascending parietal) convolution. The motor region was wholly situated in front of the fissure of Rolando and was mainly found on the ascending frontal convolution, the aspect of this convolution which looked into the fissure of Rolando being also excitable. The order of "centres" from below upwards on the ascending frontal convolution was face and head first, then neck, shoulder, arm, thorax, abdomen, and leg. The leg area lay on the inner or sagittal face of the convolution. The differentiation of areas was very exact and no inexcitable zones were found between. The fissure of Rolando showed two well-known distinct bends—the upper and the lower genu. The neck area lay precisely opposite the lower bend and the trunk area opposite the upper. Strictly circumscribed ablation of the arm or leg areas gave rise to accurately limited paralyses in the limbs in question which disappeared in about five weeks. No paralysis followed removal of considerable portions of the ascending parietal convolution. The degeneration which followed removal of the arm area was traced down the cord as far as the middle of the thoracic segment. In the cervical region in addition to degeneration in the crossed pyramidal tract a well-defined degeneration was seen in the antero-mesial zone of the same side. The higher monkeys resembled man, therefore, in possessing a homolateral pyramidal tract. Degeneration from destruction of the leg area passed down to the upper part of the lumbar enlargement, but no alteration was seen in the homolateral pyramidal tract after this lesion. Similar results were obtained from all the brains of the higher apes examined. Professor Sherrington and Dr. Grünbaum then instituted comparisons with those of the rhesus and callithrix monkeys and found that in these animals likewise no movement was obtainable with ordinary strengths of current from excitation of the ascending parietal convolution. They supposed, therefore, that such movements as had previously been observed by other investigators must have been due to the employment of currents strong enough to spread forward to the ascending frontal convolution. An attempt was made to bring one of the chimpanzees operated upon to the Congress, but unfortunately the animal died *en route*.

### *Intraocular Section of the Optic Nerve in the Rabbit.*

Dr. G. MARENGHI (Padua) exhibited a rabbit on whom he

had performed the above operation. Previous observers had divided the nerve within the orbital cavity and had invariably obtained dilatation of the pupil with total loss of reflex constriction to light. This result Dr. Marengi attributed to unavoidable injury caused to other nerves, as well as vascular disturbances inseparable from the intra-orbital method of operation. In the animal exhibited a distinct but slow reflex constriction of the pupil on exposure of the eye to light was present. This was found in all the animals experimented upon. Even weak light produced an effect. The reaction was to be explained by supposing the existence in the higher animals, as had been proved for the lower, of a peripheral reflex mechanism. Nerve-cells in all probability existed in the retina whose protoplasmic processes were sensitive to light, while their neurons were in some way connected with intrinsic ocular muscles. This latter question was, however, the subject of further observations.

*Excision of the Superior Cervical Ganglion of the Sympathetic.*

Professor LANGENDORFF (Rostock) related two instances in which he had succeeded in removing or cutting out of activity the above ganglion and which were followed by restoration of the sympathetic ocular paths. The animals employed were cats, and in one instance the ganglion was circumscribed by tightly drawn ligatures; in the other it was wholly removed. In the latter instance the paralysis had almost completely disappeared at the end of 105 days, but returned in the most obvious manner after section of the sympathetic nerve in the middle of the neck. Moreover, stimulation of the upper segment of the divided nerve yielded all the eye effects of excitation of the normal nerve, including dilatation of the pupil and enlargement of the palpebral fissure. No regeneration of the ganglion cells could have taken place, and Professor Langendorff supposed that the regenerated pre-ganglionic fibres must have made their way past the superior cervical ganglion to the muscular end organs, possibly finding more peripherally situated nerve-cells on their path around which they arborised.

*On Left-Handedness.*

Professor OSAWA (Tokio) found that many animals exhibited marked right- or left-handedness. Monkeys as a rule were either right-handed or ambidextrous, a very small number only being left-handed. Birds which used their claws for the purpose of holding food nearly always employed the left foot. The cause of right- or left-handedness in man was therefore to be sought, not alone in the study of the development of mankind, but much more in that of the lower animals.

**ENTRANCE SCHOLARSHIPS AND CERTIFICATES.—**

At Guy's Hospital Medical School the following entrance scholarships and certificates have been awarded:—Senior Science Scholarship for university students, £50, Mr. A. F. Hertz, Magdalen College, Oxford; and certificates to Mr. W. M. Mollison, King's College, Cambridge; and Mr. E. C. Hughes, Clare College, Cambridge. Junior Scholarships in Science: Mr. P. S. Mills, Dulwich College, and Mr. W. H. Trethowan, Plymouth Technical School and Guy's Hospital, £105 each; and a certificate to Mr. C. M. Wenyon, University College, London. Entrance Scholarships in Arts: £100, Mr. C. Mayer; £50, Mr. M. J. Rattray, King's School, Bruton, Somerset; and certificates to Mr. T. E. A. Carr, Lancing College, Sussex, and Mr. K. J. Saunders, Clifton College.—At the London Hospital Medical College the following entrance scholarships have been awarded:—Price Scholarship in Science, value £120, Mr. J. Owen; Price Scholarship in Anatomy and Physiology (open to students of Oxford and Cambridge only), value £60, Mr. Theo. Thompson; Entrance Science Scholarship, value £60, Mr. A. H. Pollard; Entrance Science Scholarship, value £35, Mr. E. H. R. Harris; Epsom Scholarship, value £126, Mr. S. H. Scott.—At St. Thomas's Hospital Medical School the Entrance Scholarship in National Science of the value of £150 has been awarded to Harold Beckwith Whitehouse, and the University Scholarship, of the value of £50, to George Rammell Footner, B.A., of Pembroke College, Cambridge.—At the Charing-Cross Hospital Medical School the following entrance scholarships have been awarded: Epsom scholarship (121 guineas), Mr. Edward H. Hugo; Mr. W. W. D. Chilcott, 60 guineas; Mr. W. K. Beaman, 55 guineas; Mr. B. W. Cherrett, 40 guineas; Mr. A. C. Bartlett, 30 guineas; and Mr. G. W. Rogers a Universities Exhibition of 30 guineas.

# Looking Back.<sup>1</sup>

FROM

THE LANCET, SUNDAY, OCTOBER 5, 1823.

## PREFACE.

It has long been a subject of surprise and regret, that in this extensive and intelligent community there has not hitherto existed a work that would convey to the Public, and to distant Practitioners as well as to Students in Medicine and Surgery, reports of the Metropolitan Hospital Lectures.

Having for a considerable time past observed the great and increasing inquiries for such information, in a department of science so pre-eminently useful, we have been induced to offer to public notice a work calculated, as we conceive, to supply in the most ample manner, whatever is valuable in these important branches of knowledge;—and as the Lectures of Sir Astley Cooper, on the theory and practice of Surgery, are probably the best of the kind delivered in Europe, we have commenced our undertaking with the introductory Address of that distinguished professor, given in the theatre of St. Thomas's Hospital on Wednesday evening last. The Course will be rendered complete in subsequent Numbers.

In addition to Lectures, we purpose giving under the head, Medical and Surgical Intelligence, a correct description of all the important Cases that may occur, whether in England or on any part of the civilized Continent.

Although it is not intended to give graphic representations with each Number, yet, we have made such arrangements with the most experienced surgical draughtsmen, as will enable us occasionally to do so, and in a manner, we trust, calculated to give universal satisfaction.

The great advantages derivable from information of this description, will, we hope, be sufficiently obvious to every one in the least degree conversant with medical knowledge; any arguments, therefore, to prove these are unnecessary, and we content ourselves by merely showing in what directions their utility will be most active: To the Medical and Surgical Practitioners of this city, whose avocations prevent their personal attendance of the hospitals—To Country Practitioners, whose remoteness from the headquarters, as it were, of scientific knowledge, leaves them almost without the means of ascertaining its progress—To the numerous classes of Students, whether here or in distant universities—To Colonial Practitioners—And, finally, to every individual in these realms. Consequently, we shall exclude from our pages the semibarbarous phraseology of the Schools, and adopt as its substitute plain English diction. In this attempt, we are well aware that we shall be assailed by much *interested* opposition. But, notwithstanding this, we will fearlessly discharge our duty. We hope the age of "*Mental Delusion*" has passed, and that mystery and concealment will no longer be encouraged. Indeed, we trust that mystery and ignorance will shortly be considered synonymous. Ceremonies, and signs, have now lost their charms; hieroglyphics, and gilded serpents, their power to deceive. But for these, it would have been impossible to imagine how it has happened that medical and dietetical knowledge, of all others the most calculated to benefit Man, should have been by him the most neglected. He studies with the greatest attention and assiduity the constitutions of his horses and his dogs, and learns all their peculiarities; whilst of the nature of his own he is wholly uninformed, and equally unskilled as regards his

<sup>1</sup> See Annotation, page 922.

infant offspring. Yet, a little reflection and application would enable him to avert from himself and family half the constitutional disorders that afflict society; and in addition to these advantages, his acquirements in Medical learning would furnish him with a test by which he could detect and expose the impositions of ignorant practitioners.

In conclusion—we respectfully observe, that our Columns will not be restricted to Medical intelligence, but on the contrary we shall be indefatigable in our exertions to render "THE LANCET" a complete Chronicle of current Literature.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6519 births and 3676 deaths were registered during the week ending Sept. 28th. The annual rate of mortality in these towns, which had been 19.4, 18.3, and 16.8 per 1000 in the three preceding weeks, further declined last week to 16.7. In London the death-rate was 15.0 per 1000, while it averaged 17.9 in the 32 large provincial towns. The lowest death-rates in these towns were 9.6 in Leicester, 10.5 in Croydon, 12.5 in Bradford, 12.8 in Derby, and 12.9 in Cardiff; the highest rates were 21.6 in Birmingham, 22.7 in Gateshead, 25.6 in Newcastle, and 27.3 in Sunderland. The 3676 deaths in these towns last week included 634 which were referred to the principal zymotic diseases, against 1253, 970, and 733 in the three preceding weeks; of these, 378 resulted from diarrhoeal diseases, 82 from diphtheria, 65 from "fever" (principally enteric), 37 from whooping-cough, 34 from measles, 33 from scarlet fever, and five from small-pox. The lowest death-rates from these diseases were recorded in Portsmouth, Plymouth, Halifax, and Bradford; and the highest rates in West Ham, Wolverhampton, Oldham, Hull, Sunderland, and Gateshead. The greatest proportional mortality from measles occurred in Oldham; from whooping-cough in Sunderland; from "fever" in Huddersfield, Hull, and Sunderland; and from diarrhoeal diseases in Wolverhampton, Oldham, Hull, Sunderland, and Gateshead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 82 deaths from diphtheria in these towns included 34 in London, 10 in West Ham, five in Bristol, five in Liverpool, five in Manchester, and four in Bolton. Five fatal cases of small-pox were registered in London, but not one in any other of the 33 large towns. There were 163 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, Sept. 28th, against numbers increasing from 11 to 153 on the seven preceding Saturdays; 44 new cases were admitted during the week, against 31, 62, and 37 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had been 2994, 3064, and 3098 on the three preceding Saturdays, had further risen to 3151 at the end of last week; 460 new cases were admitted during the week, against 346, 457, and 427 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 116 and 124 in the two preceding weeks, further rose last week to 137, but were 50 below the corrected average. The causes of 39, or 1.1 per cent., of the deaths in the 33 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Leeds, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, and Sheffield.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17.8, 17.5, and 16.2 per 1000 in the three preceding weeks, further declined to 16.0 per 1000 during the week ending Sept. 28th, and was 0.7 below the mean death-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12.4 in Paisley and 14.1 in Leith to 18.3 in Greenock and 18.7 in Dundee. The 509 deaths in these towns last week included 42 which were referred to diarrhoea, 12 to measles seven to whooping-cough, seven to "fever," four

to scarlet fever, and one to diphtheria. In all, 73 deaths resulted from these principal zymotic diseases, against 74 and 83 in the two preceding weeks. These 73 deaths were equal to an annual rate of 2.3 per 1000, which was 0.6 below the mean death-rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had been 38 and 53 in the two preceding weeks, declined again last week to 42, of which 22 occurred in Glasgow, seven in Aberdeen, five in Edinburgh, four in Leith, two in Dundee, and two in Greenock. The deaths from measles, which had declined from 12 to five in the four preceding weeks, rose again to 12 last week, and included 11 in Glasgow. The fatal cases of whooping-cough, which had been 10 and 13 in the two preceding weeks, declined again last week to seven, of which three were registered in Glasgow and three in Edinburgh. The deaths referred to different forms of "fever," which had been 12 and six in the two preceding weeks, rose again to seven last week, and included three in Paisley and two in Glasgow. The fatal cases of scarlet fever, which had been five, three, and two in the three preceding weeks, increased again last week to four, of which three occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 79 and 59 in the two preceding weeks, rose again last week to 101, and slightly exceeded the number in the corresponding period of last year. The causes of 12, or more than 2 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22.2 and 23.4 per 1000 in the two preceding weeks, declined again to 17.8 during the week ending Sept. 28th. During the 13 weeks of the quarter ending on that date the death-rate averaged 21.1 per 1000, the rates during the same period being 17.1 in London and 17.2 in Edinburgh. The 128 deaths of persons belonging to Dublin registered during the week under notice were 40 below the number in the preceding week, and included 17 which were referred to the principal zymotic diseases, against 35, 25, and 30 in the three preceding weeks; of these, 12 resulted from diarrhoeal diseases, three from "fever," one from scarlet fever, and one from whooping-cough. These 17 deaths were equal to an annual rate of 2.4 per 1000, the zymotic death-rates during the same period being 2.1 in London and 1.5 in Edinburgh. The deaths referred to diarrhoeal diseases, which had been 30, 22, and 20 in the three preceding weeks, further declined last week to 12. The three fatal cases of "fever" corresponded with the number recorded in the preceding week. The 128 deaths in Dublin last week included 28 of children under one year of age and 28 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Four inquest cases and two deaths from violence were registered; and 38, or nearly one-third, of the deaths occurred in public institutions. The causes of four, or more than 3 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### SOUTH AFRICAN WAR HONOURS.

The King has given orders for the following appointments and promotions in the Army in recognition of the services of the undermentioned during the operations in South Africa. They bear date 29th November, 1900.

*To be a Companion of the Order of the Bath:—*

Surgeon-Lieutenant-Colonel James Magill, Coldstream Guards.

Surgeon-Lieutenant-Colonel Magill served in the Nile expedition in 1884-85 with the Guards Camel Regiment and was present at the action at Abu Klea; severely wounded (mentioned in despatches, medal with two clasps, and Khedive's star). Principal Medical Officer, South Africa, with rank of Surgeon-Colonel.

*To be a Companion of the Order of St. Michael and St. George:—*

Surgeon-Major Walter Calverley Beevor, Scots Guards.

Surgeon-Major Beevor served in the Soudan campaign in 1885 (medal

with clasp and Khedive's star). He also served with the expedition to Ashanti under Sir Francis Scott in 1895-96 (mentioned in despatches and promoted Surgeon-Major, star). In the campaign on the North-West Frontier of India he served under Sir William Lockhart in 1897-98 as Staff Surgeon to the Tirah Expeditionary Force (mentioned in despatches, medal with two clasps).

*To be Companions of the Order of the Bath.*

Surgeon-General James Albert Clery, R.A.M.C.

Surgeon-General Clery served during the Nile expedition in 1884-85 in charge of the Abu Dom Field Hospital (medal with clasp and Khedive's star). He also served in the Soudan under Lord (Sir Herbert) Kitchener in 1898, and was present in the operations subsequent to the battle of Khartoum (mentioned in despatches, British medal and Khedive's medal).

Lieutenant-Colonel Arthur Patrick O'Connor, R.A.M.C.

Lieutenant-Colonel O'Connor served with the Burmese expedition in 1885-86 (medal with clasp).

Major (now Lieutenant-Colonel) Thomas Rashleigh Lucas, R.A.M.C.

Major Lucas served in the Egyptian war of 1882 and was present at the action of Kassassin on August 28th, and at the battle of Tel-el-Kebir (mentioned in despatches, medal with clasp, and Khedive's star). He also served in the Soudan expedition under Sir Gerald Graham in 1884 (mentioned in despatches), and was present in the engagements at El Teb and Tenuat (mentioned in despatches, two clasps). In the Nile expedition of 1884-85 he served with the Camel Bearer Company, and was present in the action at Abu Klea and in the reconnaissance to Metamneh (two clasps). He served also in the operations of the Soudan Frontier Field Force in 1885-86 and in the operations in the Northern Chin Hills, Burmah, in 1892-93 (mentioned in despatches).

Major (now Lieutenant-Colonel) Francis Augustus Bonner Daly, R.A.M.C.

Major Daly served in the Egyptian war of 1882 (medal and Khedive's star), and also served with the Soudan Frontier Field Force in 1885-86.

*To be Companions of the Order of St. Michael and St. George.*

Surgeon-General William Henry Macnamara, R.A.M.C.

Surgeon-General Macnamara served in the Egyptian war of 1882 attached to the 1st Battalion Royal Irish Fusiliers and was present at the battle of Tel-el-Kebir (medal with clasp and Khedive's star). He served also in the campaign in the Soudan under Lord (Sir Herbert) Kitchener in 1898 as Principal Medical Officer, British Brigade, and was present at the battles of the Athara (mentioned in despatches) and Khartoum (mentioned in despatches, C.B., British medal, and Khedive's medal with two clasps).

Colonel Richard Exham, R.A.M.C.

Lieutenant-Colonel John Cotter Dorman, R.A.M.C.

Lieutenant-Colonel Dorman served in the Afghan war, 1878-9, and was present in the engagement at Ali Kheyl and at the forcing of the Shutargardan (medal). He also served in the Egyptian war of 1882 (medal and Khedive's star).

Major (now Lieutenant-Colonel) Henry James Peard, R.A.M.C.

Major Samuel Foster Loughheed, R.A.M.C.

Major Alexander Fraser Russell, R.A.M.C.

Major Sinclair Westcott, R.A.M.C.

Major Roger Kirkpatrick, R.A.M.C.

Major Kirkpatrick served with the Burmese expedition in 1886-88 (medal with two clasps) and in the campaign on the North-West Frontier of India in 1897-98, under Sir W. Lockhart, with the Tirah Expeditionary Force (medal with two clasps).

Major Robert John Shaw Simpson, R.A.M.C.

Major Thomas William O'Hara Hamilton, R.A.M.C.

Major Samuel Foster Freyer, R.A.M.C.

Major S. F. Freyer served in the Soudan campaign in 1885 (medal with clasp and Khedive's star).

Major Nicholas Charles Ferguson, R.A.M.C.

Major Hugh Champneys Thurston, R.A.M.C.

Major Thurston served in the Burmese expedition in 1891 with the Wuntho Field Force (medal with clasp) and also in the South African war, 1899-1900.

Major Oliver Richard Archer Julian, R.A.M.C.

*To be Companions of the Distinguished Service Order.*

Major Robert James Geddes, R.A.M.C.

Major Geddes served in the South African war in 1899-1900 and was present in the engagement at Klip Drift, the operations of Paardeberg, including the engagement at Kitchener's Kopje, the engagement at Driefontein, and the occupation of Bloemfontein.

Major Alexander Arthur Sutton, R.A.M.C.

Captain Frederick Smith, R.A.M.C.

Captain Smith served in the Zulu war in 1879 (medal with clasp) and in the Boer war of 1881.

Captain Henry Jules Parry, R.A.M.C.

Captain Frederick Joseph William Porter, R.A.M.C.

Captain Herbert John Martin Buist, R.A.M.C.

Captain Buist served in the campaign on the North-West Frontier of

India under Sir William Lockhart in 1897-98 with the Malakand Field Force (mentioned in despatches, medal with two clasps).

Captain Edgar Montagu Pilcher, R.A.M.C.

Captain Pilcher served in the campaign on the North-West Frontier of India under Sir William Lockhart in 1897-98 with the Tirah Expeditionary Force (medal with two clasps).

Lieutenant (now Captain) Charles John O'Gorman, R.A.M.C.

Lieutenant (now Captain) Robert Strickland Hannay Fuhr, R.A.M.C.

Lieutenant George Goslett Delap, R.A.M.C.

Lieutenant Howard Ensor, R.A.M.C.

Lieutenant Langford Newman Lloyd, R.A.M.C.

*To be Majors.*

Captain S. G. Moores, R.A.M.C.

Captain Moores served with the Chitral Relief Force under Sir Robert Low in 1895 in medical charge of the 1st Battalion Gordon Highlanders and No. 8 Mountain Battery Royal Artillery (medal with clasp), also in the South African war 1899-1900 with the Kimberley Relief Force attached to the Scots Guards and was present in the engagements at Belmont, Enslin, and Modder river—wounded (mentioned in despatches)—Magersfontein, the march to Bloemfontein, the engagement at Diamond Hill and operations at Belfast, and the advance to Koomati Poort.

Captain J. H. E. Austin, R.A.M.C.

Captain Austin served in the campaign in the Soudan under Lord (Sir Herbert) Kitchener in 1898 (British medal and Khedive's medal).

*To have the Honorary Rank of Major.*

Quartermaster and Honorary Captain T. E. Kennedy (now retired pay), R.A.M.C.

*To have the Honorary Rank of Captain.*

Quartermaster and Honorary Lieutenant S. Duffield (since deceased), R.A.M.C.

Quartermaster and Honorary Lieutenant F. Crookes, R.A.M.C.

*To have increased rate of pay under Article 232, Royal Warrant for Pay, &c. :—*

Quartermaster and Honorary Captain E. Thowless, R.A.M.C.

Quartermaster and Honorary Lieutenant (now Honorary Captain) J. Hirst, R.A.M.C.

Quartermaster and Honorary Lieutenant A. Bruce, R.A.M.C.

Quartermaster and Honorary Lieutenant J. C. B. Whitehorn, R.A.M.C.

Quartermaster and Honorary Lieutenant F. Bruce, R.A.M.C.

Quartermaster and Honorary Lieutenant T. Exton, R.A.M.C.

Quartermaster and Honorary Lieutenant T. J. Jacomb, R.A.M.C.

Quartermaster and Honorary Lieutenant A. H. H. Niblett, R.A.M.C.

*The following members of the Royal Army Medical Corps to have the Distinguished Conduct Medal :—*

First-class Staff-Sergeant-Major J. de Stewart, Sergeant-Major R. Watson, Sergeant-Major A. R. Titchener, Sergeant-Major D. Roberts, Sergeant-Major F. B. Bowyer, First-class Staff-Sergeant F. H. Dolman, First-class Staff-Sergeant J. R. Gibbons, First-class Staff-Sergeant C. W. Measures, Second-class Staff-Sergeant N. Cornell, Second-class Staff-Sergeant T. Johnstone, Second-class Staff-Sergeant H. Lattemore, Second-class Staff-Sergeant F. S. Marsland, Second-class Staff-Sergeant J. Hampton, Second-class Staff-Sergeant R. Burrows, Staff-Sergeant C. H. Cooper, Sergeant T. H. V. Coad, Sergeant J. Leonard, Sergeant J. Bright, Sergeant E. I. Cadogan, Lance-Sergeant T. Davey, Lance-Sergeant F. G. Bright, Corporal W. H. Servey, Private A. Nunns, Private J. Harvey, Private M. T. Sparkes, Private H. Burford, Private R. N. Macgregor, Private (Hospital Orderly) D. Stuart attached, and Private (Hospital Orderly) F. W. Woodier attached.

IRISH HOSPITAL.

*To be Companions of the Order of St. Michael and St. George :—*

The Honourable Rupert Edward Cecil Guinness.

Mr. George Stoker.

Dr. James Byrne Coleman.

LANGMAN'S HOSPITAL.

*To be a Companion of the Order of St. Michael and St. George :—*

Dr. Herbert Johann Scharlieb.

*To have the Distinguished Conduct Medal:—*

Private E. H. G. Wynyard, St. John Ambulance Brigade.

## YEOMANRY HOSPITAL.

*To be a Companion of the Order of St. Michael and St. George:—*

Major Charles Stonham.

*To have the Decoration of the Royal Red Cross:—*

Beatrice Constance (Lady Chesham); Miss Catherine Emelia Nisbet; Miss Mary C. Fisher.

## WELSH HOSPITAL.

*To be a Companion (Civil Division) of the Order of the Bath:—*

Mr. John Lynn Thomas.

*To be a Companion of the Order of St. Michael and St. George:—*

Mr. Robert Herbert Mills-Roberts.

*To have the Decoration of the Royal Red Cross:—*

Miss Marion Lloyd.

## PRINCESS CHRISTIAN'S HOSPITAL.

*To be Companions of the Order of St. Michael and St. George:—*

Mr. Alfred Moseley.

Mr. Frank Stevens.

*To have the Decoration of the Royal Red Cross:—*

Sister Eleanor Constance Lawrence.

## EDINBURGH HOSPITAL.

*To be a Companion of the Order of St. Michael and St. George:—*

Dr. Francis Boyd.

*To have the Decoration of the Royal Red Cross:—*

Sister Annie Warren Gill.

## SCOTTISH NATIONAL HOSPITAL.

*To be a Companion of the Order of St. Michael and St. George:—*

Deputy-Surgeon-General Henry Cayley, Honorary Surgeon to the King (late Indian Medical Service).

## PORTLAND NATIONAL HOSPITAL.

*To be a Companion of the Order of St. Michael and St. George:—*

Dr. Joseph Ernest Goodfellow Calverley.

*To have the Decoration of the Royal Red Cross:—*

Nurse Edith Pretty.

## LADYBRAND.

*To have the Decoration of the Royal Red Cross:—*

Miss Julia Underwood.

## LADYSMITH.

*To have the Decoration of the Royal Red Cross:—*

Mrs. Eugénie Ludlow.

## MAFEKING.

*To have the Decoration of the Royal Red Cross:—*

Lady Sarah Wilson, Mother Superior Teresa, Miss Hill, Miss Craufurd.

*To have the Decoration of the Royal Red Cross:—*

The Hon. Mrs. Agnes Mary Goldmann, Mrs. Gunning, Mrs. Maasdorp, Mrs. Wilman, Miss Cairncross.

## COLONIAL FORCES.

*New South Wales Contingent.**To be a Companion of the Order of the Bath:—*

Major W. L'Estrange Eames (Medical Corps).

## ROYAL NAVY MEDICAL SERVICE.

Notice is given in the *London Gazette* to the officers, seamen, and marines who took part in the operations in South Africa between Oct. 11th, 1899, and March 8th, 1901, that the special gratuities awarded for the same are now in course of distribution in the Prize Branch of the Department of the Accountant-General of the Navy, Admiralty, S. W.

## Correspondence.

"Audi alteram partem."

## "ON THE PROPHYLAXIS OF CARCINOMA."

*To the Editors of THE LANCET.*

SIRS,—I should like to have permission to refer to several communications on this subject.

1. With regard to Dr. Craigie Gray's interesting letter in THE LANCET of Sept. 21st, it appears that milk and its products are not used, except a little condensed milk, in the towns of North China, but that Dr. Gray has often seen carcinoma of the lip, breast, and penis in the mission hospitals there. The hypothesis I put forward for examination was that the secretions of the skin glands may be a vehicle for conveying the cancer germ. The mammary is only one of these glands, though, of course, in some respects the most important. Sweat, sebaceous matter, and smegma præputii cannot be unknown in North China. What would be really interesting to learn is the comparative frequency of cancer of the alimentary canal in the port of Newchwang, where, according to Dr. Gray, no milk or milk products "exist," and in a country like England, where they are staple articles of diet. And to be of real value not the statement of an impression but figures and various details should be given—e.g., we should wish to know if the mission hospitals of northern Chinese ports are confined to the townspeople only. Of one thing we may be certain—viz., that whether it is used as food or not by adults there must be a great deal of milk in northern China, as the women and inferior female mammals are not likely to secrete green tea for their suckling offspring. And although most of the milk may be consumed by the young, some of it must be spilt on clothes, and that the cancer germ can pass alive right through the alimentary canal of adults is shown by the occurrence of carcinoma of the sigmoid flexure and rectum. In this connexion it would be interesting to know what are the habits of the northern Chinese as regards cleanliness?

2. I have received a very interesting letter from Dr. C. N. Saldanha. He says that the Hindoos suffer comparatively little from cancer and that they are the greatest milk-consumers in the world, but that the milk is universally boiled. They also eat a great deal of ghee or clarified butter. A bath before a meal is enjoined by their religion, "and even the poorest slave bathes once a day." They also wear either light clothing or none at all. Dr. Saldanha contrasts this with the "skin sodden with sweat, the shed epidermis, and the warm, heavy underclothing" of many Europeans, especially the working-classes. There is a letter from Dr. Saldanha on the subject of the Social Factor in the Genesis of Cancer in THE LANCET of April 28th, 1900, p. 1246.

3. With reference to my hint that "lanolin" might easily prove a favourable medium for the protection, if not for the culture, of any organism which lives in sweat glands or milk follicles, the original manufacturers of lanolin have courteously sent me "a compilation of the works on lanolin, published 1885-1892 in the medical journals" (Berlin, 1892) containing high authority for regarding lanolin as not only aseptic but antiseptic. But I cannot help being struck by Article 72 of this pamphlet: "Lanolin as a Vehicle for Vaccine Lymph," by Surgeon-Major M. G. King. The author states that "mixtures consisting of one part of" (vaccine) "pustular contents with four parts of lanolin were always preserved for at least 40 days." So that lanolin, while opposed to septic organisms, is actually protective of the vaccine virus. I have found nothing in the compilation to show how lanolin behaves to the cancer organism, whether it protects it as it does vaccinia or obstructs it as it does common septic micrococci. Lanolin is in some respects so valuable a substance that I should be sorry to do it an injustice.

4. I learn that Lyon<sup>1</sup> analysed the cancer mortality record of the City of Buffalo Board of Health and found a marked concentration in the German wards. The Germans and Poles were distinguished by the very large number of cases of cancer of the stomach and the comparatively small

<sup>1</sup> American Journal of the Medical Sciences, June, 1901.

number of cases of cancer of the uterus and breast. Lyon considers that the figures support the idea that the peculiar diet of the Germans is responsible for the high rate amongst them.<sup>2</sup>

After a review of such information as has been given me since my paper appeared in THE LANCET of August 31st I do not think that the hypothesis I submitted for examination has been seriously shaken, and it seems to receive a certain small measure of support from some of the facts stated—e.g., the freedom of the Hindoos from cancer and their carefulness to boil their milk and cleanse their skins, and by the apparent relationship to diet of some kind indicated by Dr. Lyon's Buffalo figures.

I am, Sirs, yours faithfully,  
Sept. 30th, 1901.

C. B. KEETLEY.

## THE COMING ELECTION TO THE GENERAL MEDICAL COUNCIL.

To the Editors of THE LANCET.

SIRS,—Acting as secretary *pro tem*. I beg to inform you that a meeting of the profession in the north is being arranged in connexion with the approaching election to the General Medical Council. The County of Durham Medical Union has taken the initiative and has already been promised the coöperation of the North of England Branch of the British Medical Association, the Northumberland and Newcastle Medical Association, and the Gateshead Medical Association. There is no doubt that the other associations in the district will assist in making the meeting large and representative. In order to save the time of candidates for the Council and to give them an opportunity of easily reaching as large a number as possible of the electors, it is proposed to ask every candidate to come to the proposed meeting which will be arranged for a date in October. This meeting, which will be held in Newcastle, will offer to each candidate an opportunity to state his views and make the personal acquaintance of a section of the electors. The meeting will, we hope, have the effect of increasing the interest in the election and of ensuring a good local vote.

I am, Sirs, yours faithfully,  
Gateshead, Sept. 27th, 1901.

ALFRED COX.

## "APPENDICITIS."

To the Editors of THE LANCET.

SIRS,—Having read with considerable interest Mr. F. G. Lloyd's excellent article on Appendicitis, some General Remarks on its Pathology and Treatment, which appeared in THE LANCET of Sept. 21st, p. 788, it has occurred to me that he has passed over what may be one of the primary causes of this not uncommon trouble. For some time past it has been in my mind that the starting-point is due to defective digestion brought about frequently by imperfect mastication of food. The undigested portions decomposing in the bowel generate gas which distends the cæcum; this distension naturally opens wide the orifice of the appendix vermiformis, into which faecal substance is allowed easily to enter. The gas passing away and the orifice contracting the contained matter is thus retained. The appendix, endeavouring to expel it by its vermicular movements, squeezes out the fluid parts, but the more solid portion remains behind and becomes the concretion which is so frequently found as the cause of the inflammation which has necessitated operation. In many cases the primary attack subsides until another cæcal distension takes place with a recurrent "appendicitis," and in one of these attacks of distension it is easily conceivable that a foreign body, such as any of those so well illustrated in the *Johns Hopkins Hospital Bulletin* for January-March, 1899, may enter and give rise to violent inflammation and be found at the time of operation. In a recent case in my practice a faecal concretion of the shape of, and as large as, a monkey-nut was discovered together with two cherry-stones. The patient underwent operation; the appendix was excised and he made a good recovery. Whether this suggestion is original I am not prepared to say, but so far I have not seen attention drawn to it as a cause.

I am, Sirs, yours faithfully,  
HERBERT J. CAPON.  
Upper George-street, W., Sept. 29th, 1901.

<sup>2</sup> Brit. Med. Jour., Sept. 21st, 1901.

## "WORKHOUSE NURSING."

To the Editors of THE LANCET.

SIRS,—Through the courtesy of Miss Louisa Twining I have been able to confirm that which I had previously suspected—viz., that Mr. F. R. Humphreys has annexed and labeled as "my (Mr. Humphreys's) scheme" the plan formulated by Miss Twining and published by her in July, 1901. I have no intention, therefore, of discussing the matter further with Mr. Humphreys, but as that gentleman has represented me as holding views entirely contrary to my expressed opinions I must ask you to allow me to correct his statements.

In my last letter, after stating that nurses in the smaller infirmaries were not well paid and were badly governed, I expressed the opinion that with adequate salaries and proper government there would be no lack of good nurses. In the face of this Mr. Humphreys accuses me of holding exactly diverse opinions and bombards me with extracts from the reports of Local Government Board inspectors, with every one of which I entirely agree. Either Mr. Humphreys is obtuse or he represents me as holding opinions contrary to the actual facts that he may have the easy advantage of controverting them. Mr. Humphreys also represents me as advocating the employment of untrained nurses, whereas I expressly stated that I admitted the advisability of having highly trained nurses, a statement which Mr. Humphreys has omitted to quote; and I endeavoured to make it perfectly plain that the suggested massing together of the sick would not supply the requisite material for the efficient training of nurses, but would result in the production of a fraudulently hall-marked article. Mr. Humphreys accuses me of contradicting myself when I say that the larger infirmaries train their nurses thoroughly. It is difficult to argue with one who knows so little of his subject as to be unable to distinguish between a large infirmary situated in the midst of its district and containing many acute medical and surgical cases and that of a small country infirmary miles away from the homes of its patients.

The term "pioneer work" as applied to the efforts of the Workhouse Infirmary Nursing Association is simply a cant phrase, and the fact remains that it committed suicide because it had become so distrusted, and had by the underhand methods of its nurses excited so much antagonism that it could no longer continue its career.

I am, Sirs, yours faithfully,  
F. S. TOOGOOD, M.D. Lond.,  
Medical Superintendent, Lewisham Infirmary, S.E.  
Sept. 30th, 1901.

## "THE PROSPECT OF CURE IN CANCER."

To the Editors of THE LANCET.

SIRS,—In confirmation of the views expressed by Dr. Horace Manders in THE LANCET of Sept. 28th may I be allowed to state that it has recently been my privilege to be a disinterested, and I hope impartial, observer of a number of cases of cancer and of pulmonary tuberculosis which are at the present time undergoing treatment without the aid of drugs at the hand of a physician and an expert in electrical science, whose desire it is that their names should for the moment not be divulged?

The cases of tuberculosis are all in the stage of cavitation; those of cancer have, with one exception, been pronounced by authorities well known to the medical world to be hopeless. Of all those which have been more than a week under treatment I am in a position to say that, both as to local conditions and general health, they are in a state which, to all appearance, is one of imminent cure. Very shortly—probably before many weeks have passed—you will be invited to give to the medical profession a full statement of these cases and a detailed account of the means and methods which are being brought to bear on their treatment.

I am, Sirs, yours faithfully,  
Sept. 30th, 1901.

W. BEZLY THORNE.

## THE OUTBREAK OF SMALL-POX IN SOUTH AUSTRALIA.

To the Editors of THE LANCET.

SIRS,—The account of the outbreak of small-pox by your Australian correspondent in THE LANCET of July 27th, p. 253, is correct in the main but erroneous in some particulars, especially where it states, "When the Adelaide passengers

had been 11 days in quarantine Dr. Ramsay Smith advised that they should be released and kept under surveillance." This is not so. What I did was to recommend the removal to comfortable quarantine quarters elsewhere of certain persons sick, but not from small-pox, who had been certified as medically unfit for detention on Torrens Island. This removal was accomplished as soon as the weather permitted. These persons, like the other contacts, served their legal period of detention, for whatever my personal views of quarantine in general may be I have to carry out the laws in particular that refer to this State. The statement that a constable developed the disease at Adelaide is incorrect.

The muddles your correspondent refers to existed (1) in the imaginations and reports of some newspaper correspondents who knew neither laws nor science; (2) the misstatements founded thereon by an Adelaide medical gentleman; and (3) in an alleged interview of a newspaper correspondent with the president of the Board of Health at Sydney who afterwards affirmed that he had never given any foundation whatever for the statements regarding blundering at Adelaide attributed to him in that interview. Unfounded criticisms of this sort regarding official action are ignored when they appear in the lay press; but they should not be allowed to gain currency by being repeated unchallenged in professional journals.—I have the honour to be, Sirs,

Your obedient servant,

W. RAMSAY SMITH, M.B., C.M., B.Sc. Edin.,  
President of the Central Board of Health for South Australia.  
Adelaide, August 28th, 1901.

## THE OPEN-AIR TREATMENT OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In a previous communication to you—published on May 20th, 1899, p. 1409—I recorded a case of early phthisis in a young woman which showed marked improvement and eventual recovery under treatment by high feeding and fresh air. I have recently seen this case again and the improvement has been permanent. The patient looks the picture of health, takes long bicycle rides, and has neither felt sick nor sorry during the time—a period of two years and four months.

As I mentioned then, tuberculosis in any form is quite a rarity in this district and hitherto only a few cases, comparatively speaking, have come under one's care from other places, and from various causes they generally stay but a short time; unfortunately, too, one hears little or nothing of their subsequent history, and it is satisfactory to find as above that the treatment is, at any rate in some, a means of permanent cure. All early cases invariably show marked improvement, and I have now a patient who is responding to treatment in a fashion astonishing both to her relatives and myself. The patient, a married woman, aged 42 years, was ordered away by her medical man for phthisis of the lung, as her best chance. The lung is affected as low as the nipple and the drenching sweats, loathing of food, anæmia, and utter listlessness combined made as sorry a picture as one need wish to see. Walking and movement caused much distress. The house she is staying at is on clay in the lowest-lying part of the village and the situation is not the most suitable for the open-air treatment. However, the trial has been most satisfactory, as in 15 days she has gained a stone in weight with corresponding improvement in every other respect, including the ability to walk quite a fair distance without trouble. It is too early to give a good definite prognosis, but so far the satisfactory progress of the case speaks well for high feeding and fresh air in suitable cases even in private houses not in the best of positions. I feel sure that the enormous rise and fall in the tide here by causing a continual change of air is responsible not only for the healthy condition of the population, but also for the happy results obtainable in early cases of phthisis.

I am, Sirs, yours faithfully,

GEORGE BOYD, M.R.C.S. Eng., L.R.C.P. Lond.  
Portishead, Somerset, Sept. 28th, 1901.

## "FRENCH AND BRITISH POSTAL MEDICAL SERVICES: A COMPARISON."

To the Editors of THE LANCET.

SIRS,—Your Special Commissioner in his article in THE LANCET of Sept. 21st, p. 806, upon the above subject has contributed an extremely well-informed and interesting account, so far, at any rate, as London is concerned. May

I, as postal medical officer to a large and important London district, make a few observations thereon?

Of the French system I know nothing beyond what I have read in your Commissioner's admirable article, but I gather that part of the French system at least is of comparatively recent establishment (May 19th, 1900), and whether a sufficient length of time has elapsed to prove its efficiency and whether the medical service there works as smoothly and easily as the easy flow of your Commissioner's remarks appears to suggest I cannot say, but I think it at all events merits the query. The system is certainly ingenious and, compared with our "rough-and-ready method," which is simple if not original, looks somewhat complicated.

"The most serious defect of the British system," says your Commissioner, "is that the 8s. 6d. per annum has to meet every conceivable circumstance that may arise." "If a serious surgical operation is needed this must be performed, &c., &c." Theoretically this may be so; 8s. 6d. per officer per annum is paid for medical attendance, but surely for medical attendance only so far as a medical officer's ability goes. The postal authorities certainly do not expect them to undertake serious surgical operations. There is no such stipulation made in the instructions issued to medical officers on appointment; they are simply required to do their best for their patients in promoting their recovery and their speedy return to duty. Obviously their best would not be the undertaking of a serious operation of which they have had probably little or no experience. I should be exceedingly surprised also to learn that they (the postal authorities) have ever required a medical officer to provide a surgeon for such operation at his own expense. Not many surgeons, I imagine, would care to undertake a serious operation in the home of a postman in London with all the attendant difficulties in the matter of space, ventilation, cleanliness, and nursing, and I doubt whether competent surgeons could ever be induced to visit and to operate at anything like the scale of fees mentioned by your Commissioner. We have different ideas as to operation fees here in England.

And why should not postal officials be the recipients of hospital charity if necessary? They surely have as much right to it according to their station in life as other members of the community. In most offices they subscribe to the Hospital Saturday Fund, and the late Postmaster-General was in the habit of specially subscribing to certain London hospitals, so we were given to understand, because he recognised the fact that from time to time cases arose amongst the officials that could only be treated satisfactorily in hospital. Only such cases as really require hospital attention are sent there and hospital authorities at least know they are proper cases for relief. In an experience of eight years I have never known any difficulty arise in such cases.

Again, your Commissioner says: "There is such a delightful and lazy simplicity about the 8s. 6d." Why lazy? I think it would strike most people as a simple, practical, common-sense method of remuneration for services, generally admitted, I believe, to be exceedingly well performed. Why should one complain if a Government Department for once in a way does do a practical common-sense stroke of business? Government does not often get credit for so doing. Your Commissioner says that it is not common-sense and he would introduce the intricacy and elaborate detail of the French system. But it does not follow that a system which may answer admirably in Paris would be equally applicable in London. Some few years ago a commission was appointed to investigate post-office methods and grievances of officials, and the question of officials being attended by the medical officer of their own home district was then raised and, after consideration, the idea was rejected. The postal medical officer's duties do not merely consist of attendance upon the sick. He has to be in touch with his district offices, he has to be familiar with their working arrangements, and their sanitary condition is his special care; he is more or less acquainted with the officers employed there and he has to make reports, suggestions, and give advice from time to time concerning them and their duties. If an official is being attended privately and the illness is of any considerable duration it is the medical officer's duty to make himself acquainted with the case and to be prepared to give an opinion upon it. He is to a certain extent responsible for the amount of sickness, or, at all events, is expected to be able to account for any excess of sickness in his district. These are his duties and responsibilities; they mean a great deal more than mere sick attendance. The Department recognises that much is required

of him and has been pleased from time to time of late to enhance his emolument of 8s. 6d. per head by certain extra payments as mentioned by your Commissioner. But it certainly does not expect him to do impossibilities with his not very extravagant salary.

Almost the only difficulty that faces the postal medical officer is his dealing with the private medical attendant of an official. Friction and unpleasantness do undoubtedly occasionally arise, but I have always found that with courtesy and a little tact misunderstanding is easily removed, and my own relations with these gentlemen have always been of the pleasantest. The post-office official of the rank entitled to gratuitous medical attendance is an individual who is fond of changing his abode. He is allowed to reside where he pleases within three miles of his office; by special permission he sometimes goes much further afield. Many of them change their residence half-a-dozen times in as many years, some even oftener than this. Under the French system, then, how many different official medical attendants he may have in the course of a few years. How various may be the opinions expressed about him, and all responsible official opinions. One year he may reside south of the Thames, another in the north district, and another even as far away as Ealing or Balham. The interminable official correspondence, here and there, that would inevitably arise from such a system as this can perhaps only be properly appreciated by the official mind.

It is in his comparison of the two services that I disagree with your Commissioner; with the rest of his article I entirely agree. The French service is unquestionably superior in elaborate detail, but elaborate machinery is usually the most prone to breakdown. Our system is admittedly not perfect, but it answers its purpose very well. The medical officers are perhaps not very extravagantly remunerated—some of us may even at times grumble a little, but on the whole we are fairly content. The work is interesting and instructive and the grave and terrible responsibilities described by your Commissioner as hanging over our heads and making our lives a burden are so remote that they may assuredly be disregarded.

I am, Sirs, yours faithfully,

London, Sept. 25th, 1901. A POSTAL MEDICAL OFFICER.

## OUTBREAK OF PESTIS BUBONICA AT NAPLES.

To the Editors of THE LANCET.

SIRS,—Grave doubts are entertained in well-informed professional circles whether the cases described as those of pestis bubonica cases, the occurrence of which has thrown southern Italy into panic and is at the present moment inspiring the most drastic measures at headquarters, come really under the category of pestis bubonica at all. Scarcely had the first intimations of the outbreak been made public when Professor Alessandro Lustig of Florence, who has studied the plague at Bombay from 1897 to 1899 and has devised a special vaccine for its treatment, announced that 24 hours would make it evident whether or no the Neapolitan medical officers had been justified in their diagnosis. Well-nigh a week has elapsed and we are still without the data on which a satisfactory judgment can be formed. The press is complaining loudly of this official delay, and meanwhile it may be well to recapitulate the facts partially known but thoroughly vouched for as to the circumstances in which the outbreak first appeared.

Last week the primary indications of something resembling pestis bubonica were suspected on board the steamship *Adria* (formerly known as the *Ortigia*). She had touched at various ports in the Levant and had taken in some families fleeing in alarm from Egypt and Tunis, where the plague was believed to be prevalent. The vessel had as part of its cargo 24 bales of cotton, and considering that its point of departure was Bombay it should not have been allowed "libera pratica" (free course). The sanitary authorities seem to have thought otherwise and in point of fact both cargo and passengers were permitted to be put on shore, the former at Punto Franco, the latter at Naples. Within the same week another steamship hailing from Calcutta, with a cargo of hides, touched at Alessandria (Egypt), by which time the hides were in such an advanced state of putrefaction that they were not allowed to be landed. The vessel proceeded to Marseilles, where again the hides were refused admittance. At Genoa, the

next port it touched at, the same prohibition was practised. Finally, at Naples, its next place of call, "o per incuria o per inframettenza di qualcuno" (either through carelessness or the intercession of some interested party), the hides, by this time in a highly dangerous condition, were disembarked and deposited at Punto Franco for retransmission to Alessandria, for which they were originally destined. This proceeding was, it is said, reported to the Prefect when holding an official investigation, and a committee acting under him is inquiring diligently into the sanitary service of the port.

One can understand the anxiety of all interested in the sojourn of strangers in Italy—a source which from the English-speaking world alone brings in £20,000,000 annually—to minimise the facts as much as possible. But, however inspired, "suppressio veri" is always bad policy, inevitably resulting in "suggestio falsi," or the exaggeration of the truth. Is the disease from which so many are now being treated either on board the *Oreto* or in the lazaretto of Nisida the true "pestis bubonica"? Dr. Alfonso Perrone of Naples, a highly esteemed authority, is more than doubtful on the question and thinks the symptoms are rather those of *charbon malin* or *puistula maligna*, easily communicable to man or beast by contact with certain hides known as the nidus of the bacillus special to such maladies. He supports his view by the undoubted fact that the so-called "pestis" was confined to the labourers at Punto Franco engaged in unloading the two steamships above referred to and the absolute immunity from the same symptoms of all who came near or in actual contact with those labourers when under treatment in hospital or even when being conducted to it—immunity owing nothing to prophylactic or precautionary measures, which indeed were not applied. Dr. Perrone is not alone in taking this view. Punto Franco has long been notorious for the insanitary condition of the hides discharged there. Some months ago a cargo of the same arrived in such a state of putrescence that the labourers "struck" rather than handle them, and one of the men who was prevailed upon to help in the unloading was so overcome with the fœtor that he lost consciousness with all the symptoms of asphyxia. An animated interchange of views *apropos* of Dr. Perrone's contention is in progress in the Neapolitan press, while the necropsy held by Professor Gosio, Professor Basile, Professor Cimmino, and Dr. Druetti on one of the victims who died in hospital resulted in the report that "non furono ritrovati i classici bubboni della peste, trattandosi evidentemente di una forma non ordinaria" (the typical buboes of plague were not found, the case being evidently one of an unusual form). Whatever the malady may turn out to be, it is now completely circumscribed and the latest announcements make it clear that it is not likely to extend. All the patients, it seems, are doing well, whether owing to the Haiffine vaccine, which, as prepared at the sanitary station on the island of Pianosa, has been generally used, or to the sedulous clinical care bestowed, it is difficult to say. Naturally enough the friends of Professor Lustig are inquiring whether his vaccine, which has proved successful in Australia, where it has "had a fair trial," should not have had the preference; still more whether his opinion should not have been taken before sending to Paris for Dr. Salimbeni of the Pasteur Institute. But there are questions which must await solution when the official report is made *publici juris*.

I am, Sirs, yours faithfully,

Florence, Sept. 30th, 1901.

M.D.

## THE SERVICE ON ST. LUKE'S DAY.

To the Editors of THE LANCET.

SIRS,—In reference to the service which, I presume, will be held again this year at St. Paul's for the medical profession I beg to protest at the very unjust division of the seats for medical men. On previous occasions nearly all the front and best seats were occupied by women, young girls, and even boys, to the exclusion especially of elderly medical men, who on the last occasion were shunted to the side seats, where they could neither see anything or even hear the preacher.

As the service is understood to be solely for members of the medical profession I think it incumbent on the authorities to arrange a fairer distribution of seats.

I am, Sirs, yours faithfully,

Sept. 24th, 1901.

SURGEON-MAJOR.

## MUNICIPAL REPRESENTATIVES ON THE HOUSING OF THE POOR:

A CONFERENCE AT GLASGOW.

(FROM OUR SPECIAL COMMISSIONER.)

WHATEVER other good purpose the Glasgow Exhibition has served it has certainly been the means or pretext for ventilating the vexed question of the housing of the poor. As already described,<sup>1</sup> the engineers at their International Congress, held in connexion with the Glasgow Exhibition, had a section devoted to municipal engineering, and here the housing question was lengthily discussed. The Exhibition also attracted the British Association to Glasgow, and one of the meetings of the Association which brought together the largest number of persons was that held by the Economical Section for the purpose of debating the housing problem. On this occasion Professor Smart, LL.D., read the opening paper, contending that municipalities should only provide dwellings for the poor of the community, and it soon became evident that one of the most debateable points was the definition of the word "poor." To this word not a few speakers were tempted to prefix the descriptive adjective "deserving." Others, on the contrary, urged that it was precisely the undeserving poor who constituted the most urgent and dangerous phase of the problem. Here at once there seemed to be a conflict between sanitation and morality. Some speakers were anxious to help those who strove to help themselves, but the sanitarian pointed out that it was the degraded, the immoral, the reckless, and the shiftless who constituted the principal menace to the public health. If the rejected class, the disinherited, and the degraded could be properly housed and made to pay the rent, the rates for the poor, the police, and the sanitary rates would be considerably reduced and the danger of epidemics in a great measure set aside. For such a purpose disciplinary sanitary dwellings were required; but as they were not likely to pay their expenses the question arose as to whether a housing-rate was not as justifiable and likely to be as beneficial as the poor-rate. In the course of the discussion it was pointed out that many Clyde workers spent 6s. a week in rent, but that the publican got three-fifths as much money from them as the landlord. The difficulty rested in the fact that these people rejected any sort of discipline and to enforce discipline there should be an alliance between landlords and the municipality. Landlords—this was the general sense of the meeting—who have no appreciation of their responsibilities should be sternly punished. To let an unhealthy tenement should be just as great an offence as the selling of unsound fish or tuberculous meat. The thriftless degraded class knew no greater power than that of the landlord. The latter must be forced to insist that his tenants must behave or leave. When thus driven away a municipal shelter, at a normal rate of payment, should be open to them. No question whatsoever should be asked of the applicant, but the necessary discipline should be enforced, and any real case of poverty would be found out and relieved.

Here, then, we have a dual form of coercion proposed. The landlord is to be forced to keep his tenants in order or to eject them; the ejected tenants will find no other refuge except the municipal shelter, where, however bad their antecedents might be, they would be accepted, but where they would be compelled to pay the rent, if they had the means, and would also be compelled to keep their dwelling clean and in sanitary order. It is doubtful, however, if public opinion is ripe for the adoption of such stringent measures. Yet there was no lack of energetic denunciation of that class of individuals who were described as "a disgrace to humanity" and who were bad tenants living in bad houses under bad landlords. Then the house-farmer came in for his share of abuse. This individual would rent what is called a house in Glasgow and a flat in London, paying about £25 a year rent. Such a flat would be big enough to crowd in nine beds. Each of these beds could be let for 10d. a night, and thus a net profit of more than £100 could be realised annually out of the moral and physical wrecks lodged in a dwelling that was rented for £25. Several speakers agreed that the difficulty was with the habits of the occupants rather than with the property.

It was not the poor labouring man but the loafer and irregular worker who created the main difficulty. A respectable working man was always able to house himself, at least in Glasgow, for in London this was not always the case. The Lord Provost (Mr. Samuel Chisholm, LL.D.) spoke with much feeling on the question, and it was easy to see that with him this was an ethical problem and quite as urgent from the moral as from the material point of view. Some thought that the trouble was due to the exorbitant price of land, others that the minimum wage was based on rent, and others that all the evil was caused by drink. The Glasgow municipality believed that they had a duty to perform towards the poorest classes of the community. They had obtained an Improvements Trust Act based on the idea of cleansing the slums, leaving private enterprise to rebuild. But the speculating builders had not come forward and no offers were made for the cleared land that the municipality were able to accept. The early speculators had burnt their fingers and the others kept prudently away. A great number of the people who had been displaced in demolishing some of the slums were earning from 17s. to 18s. a week—they were poor and sober people who tried to pay their way in spite of their slender resources. Others, on the contrary, earned very high wages, but only worked about three days in the week and spent the rest of the time in idleness and dissipation. The corporation, in default of private enterprise, had themselves been compelled to build and now owned a thousand or more tenements, and they were also looking out for likely areas in the outskirts of the city. In practice the process was that of securing poor but respectable tenants. Caretakers were employed to see that the dwellings were kept clean and in good repair and to raise the moral tone of the population. Consequently the more difficult phase of the problem had not been touched, for the corporation had not attempted to provide houses for the utterly disreputable classes. This was a moral question which the municipality had failed to reach. They had dealt with houses rather than with morals and had provided what private enterprise failed to provide—namely, houses at £4 10s. per annum for people who only earned from 17s. to 20s. per week and therefore could not pay more.

Such were the main points raised at the discussion held by the British Association. It will be seen that they served rather to illustrate the difficulties of the case than to suggest a solution. Under these circumstances the "Conference as to Cheap Dwellings" followed very appropriately on the debate at the Economical Section of the British Association. Here, at last, was an opportunity of obtaining some really practical indications. This was not to be a gathering of mere theorists, of hobby-riders, or of charitably disposed persons vaguely desirous of doing something to relieve human misery, if this could conveniently be achieved without disturbing any existing institution or privilege. The Corporation of Glasgow had issued invitations to all the other corporations or the United Kingdom to send such of their members or functionaries as had acquired experience in the question of the housing of the poor. This, then, was to be a meeting of town councillors who had practically dealt with the problem, reinforced by functionaries and specialists known for their extensive experience in such matters. The conference met in the Council Hall of the Glasgow municipal buildings, or City Chambers as they are called, on Sept. 24th and 25th, and on this occasion some really practical advice ought to have been forthcoming. It was, however, somewhat disconcerting to find that speaker after speaker, while expressing his willingness to describe what had been done in his own particular locality, hastened to explain that he attended the conference for the purpose of learning. But if all had come to learn, who, then, was going to teach? Besides the representatives of the city of Glasgow there were 160 delegates from other town councils. At 10 in the morning these representatives had assembled in the Council Chamber and the proceedings were opened by the Lord Provost.

Dr. Samuel Chisholm in his inaugural speech was at least able to render this service—he gave an excellent definition of the word "poor" as applied to the housing question. He said that there was a minimum amount of house space and convenience to which every human being was entitled. The poor were those who, by reason of their poverty, would, if left to the ordinary law of supply and demand, be forced to accept less than that minimum. He frankly admitted that the action taken by the corporation was a desecration of the

<sup>1</sup> THE LANCET, Sept. 14th, 1901, p. 748.

law of supply and demand; but he urged that this law could only be allowed to exist where there was something like equality between the buyer and the seller. Generally speaking, if an article exceeded the price the purchaser could afford he might do without it or buy something else in its stead, or wait for a change in the market. This was not the case with regard to the minimum housing accommodation. As in the past the law of supply and demand had not been interfered with, the result was that houses had been built up in back courts, light and air had been shut out, and a state of things created which was a scandal and a menace to society. As individuals, as a municipality, as humanitarians, or as Christians, they could no longer afford to ignore the cry of the unhoused or of the insufficiently housed. They had to deal with two classes of people: those who had adequate wages but mispent them and those who did not, and could not, earn adequate wages to pay a sufficient rent. The former class might be left to their own devices but for their children, and it was a question whether the law should be strengthened by which children could be taken away from the control of unworthy parents. It could not be said that it was anybody's duty to provide for the needs of self-imposed and perfectly avoidable poverty.

Preceptor and Councillor GRAY (Glasgow) opened the discussion by a paper on the Cheap Acquisition of Land and Capital for Building Purposes. Out of 156,000 houses or flats in Glasgow 36,000 had but one room and 70,000 but two rooms. This showed how they had degenerated from the time when, in good Queen Anne's reign, an Act was adopted stipulating that every labourer's cottage must have an allotment of at least four acres of land. To meet the difficulty Councillor Gray appealed to the capitalist for voluntary effort which would be the noblest employment of his wealth. Then he urged that all vacant suitable lands should at once be utilised and finally he advocated municipal action. The last course should clear the land of what he qualified as "diseased" property. If corporations had to buy such erections they should not pay more than the value of the old material. They must have greater powers over landlords. The latter should have certificates of suitability and all unsuitable houses should be closed. If the landlord failed to rebuild or to repair them the property should be bought by the municipality at the value of the land and the old material. (This I may remark is something like the process adopted at Brussels and a landlord would not charge for the rental value of a house he is not allowed to rent.) Councillor Gray then proceeded to advocate in regard to land the same policy that I remember describing some 20 years ago when it was urged by the Labour representatives on the Paris municipal council. Councillor Gray insisted that on the outskirts of large towns land was held speculatively for a rise. It was high time, he said, that the powers recommended by the Housing of the Working Classes Act, 1885, and, indeed, included in one or more Bills recently before Parliament, should be pressed forward, so that ground might be more and more forced into the market. The landed gentry had driven the poor into the towns and they must now be called upon to share in solving the housing problem. (Here I may add that in Paris it was proposed to tax houses and land which were held back at the same rate as if they were occupied by tenants; and now in Glasgow the complaint is repeated that land suitable for building is held back for speculative purposes, and yet it is only taxed at one-fourth its agricultural value.) Such land must be forced into the market; the cost of transfer, said Councillor Gray, must be reduced, for "if we do not destroy the slums they will destroy us."

Councillor BURT (Glasgow) was even more emphatic. He strongly recommended the breaking-down of the monopoly in land by taxing land held idle or unoccupied. This would bring it into the market, increase the competition to secure tenants, and thus reduce rents. The municipalities of Glasgow and other towns had petitioned in this sense and a strong and united appeal should be made to Parliament. This would be no infringement on the rights of property, for the value of land was increased by the community and the community had a right to that which they created. If the land was acquired on reasonable terms there would be no difficulty in building on it, for the Corporation of Glasgow had been able to borrow money at as low a rate as seven-eighths per cent.

Mr. A. B. McDONALD, the City of Glasgow engineer, read a paper on the Material and Methods of Construction with regard

to the housing of that class which could not be made to pay the rent for model dwellings, even if this was reduced by obtaining the land for nothing. This thriftless class ignored alike decency and comfort and their homes were the normal refuge of zymotic diseases. He thought that even this class could be housed without imposing a charge on the community. The law demanded 400 cubic feet per person. In practice the sanitary inspectors had, for instance, reported a room in Marlborough-street, rented for 1s. 10d. per week, with space for three adults, but it contained six adults, four of whom were lodgers, and the space for each was reduced to 202 cubic feet. In Garngad-road in one room there were six adults and two children, reducing the space to 217 cubic feet. In South Coburg-street overcrowding brought down the average to 171 cubic feet, and in Garngad-hill to less than 100 cubic feet per tenant. There were even worse cases. By such subletting and overcrowding the rent might be reduced to 6d. per week per occupant, and of course no municipality could provide lodgings at so low a rate. He urged that such a class could only be lodged in structures of a special type, where everything would be reduced to its simplest form and consist of "a weather-proof shelter, with ample space, a water-supply, and sanitary accommodation, but little more." For this it might be necessary to obtain some relaxation of the Building Acts. Mr. McDonald submitted plans of a dwelling of three stories, with ten single-room tenements on every floor measuring 1200 cubic feet each. The walls were to be of common brick, with a hollow space for the better protection from external cold. The partitions were to be of plain brick and the floor of one room would be the ceiling of the other. There would be no laths, plaster, or other ornamentation—only the bare walls. The ground required would be 680 square yards, the structure would cost £1100, and he proposed to charge only 1s. per week per room. This would represent a rental of £78, and writing off the rental 25 per cent. and charging interest on the cost of erection at 3½ per cent. there would remain a surplus sufficient to meet a charge of 10s. per yard for the site.

The above scheme constituted one of the most practical suggestions brought forward during the entire conference. It was the lowest bid ever made. 12,000 cubic feet for 1s. per week, and this after paying 10s. per square yard for land. Everybody was anxious to see how this could be done. Such an experiment would really be something quite novel, for never had anything been achieved so economically. Of course, many doubts were expressed and gloomy forebodings entertained as to the inevitable nastiness that would be likely to characterise such very cheap dwellings.

So far only papers had been read, but now discussion was invited, and Mr. JOHN HARRISON of Glasgow commenced by complaining that the cost of building had recently increased 30 per cent.; but he urged that in many cases it was not a question of cost, but a question of improving the morals of the occupants. Miss Octavia Hill was able to obtain from the occupants of slums from 2s. 9d. to 3s. 2d. per week for a single room; and this, in spite of the high price of land, paid 4 per cent. on the capital invested. The great object was to strive to improve the habits and desires of the tenants.

Alderman NEWTON (Newcastle) objected that at Newcastle they had many slums that could not be improved in this way. There was strong medical evidence as to the moral and physical diseases that resulted from people living in an atmosphere which was so unwholesome that it endangered not only the poor but the wealthier classes who lived near them. If it was true that wholesome rooms, in which God's light could penetrate, could be rented for 1s. per week, then a great step would have been taken towards raising the submerged tenth. At present nothing had been done for less than double that price.

Councillor WALTERS (Leicester) said that all efforts were marred by the cost of the sinking fund. As the land always remained its rental value alone need be paid. Then the Local Government Board made them build walls 14 inches thick, though private speculators were allowed to build walls only nine inches thick.

Councillor MARTIN (Woolwich) was anxious that the desire to build should not interfere with the necessity of maintaining many free open spaces, and he agreed with the Lord Provost that the law of supply and demand had not operated in such a manner as to provide for the first necessities of the human family. Even if, as objected, municipal enterprise had only provided tenements for the better class of workers, still this left their former homes open

to the inferior class of workers who had thus better opportunities of getting out of the slums.

Mr. H. C. RICHARDS, M.P., thought that Parliament would be disposed to help the municipalities in their efforts to deal with the owners of slum property; but with regard to the land and the taxing of ground value to discuss that was like beating the air. Parliament would not move in the matter. He did not think that municipalities could deal with those who spent half their earnings on drink, but they could help the deserving poor, not only labourers, but poor widows, shop assistants, and other badly paid workers.

Mr. MURRAY (Tynemouth) urged that the buildings of corporations should serve as an example to private enterprise. At present the poor could not keep themselves clean. A man with a wife and four children, earning perhaps 30s. a week, would have to pay 7s. 6d. in rent alone and then there were often only a tin tub and a kettle of warm water in which to bathe the children, so that the first washed was the best washed.

Mr. CLARK (Shoreditch) complained that the delays caused by the Local Government Board had made his local authority lose seven years before they could get one set of rooms for some workers they had displaced. Further the refusal to allow shops under working-class dwellings had greatly increased the rents which they were obliged to charge.

Mr. D. S. WATERLOW, Chairman of the Housing of the Working Classes Committee of the London County Council, said that Miss Octavia Hill had argued that if land could be bought at 45s. the yard, or 5s. per square foot, much could be done in London; but land in the crowded areas of London could not be obtained at anything like that price. For clearing insanitary areas the London County Council generally paid from 15s. to 17s. per square foot. Block dwellings had to be well built, they would last at least 150 years, and therefore the capital expenditure need not be refunded under from 80 to 100 years. He cited the case of a woman who paid 6s. a week for two miserable rooms in Hackney. A new landlord came and raised the rent first to 8s. and then to 10s., which the woman was obliged to pay because she could not move. But if this was taken over as an insanitary area the compensation to be given would be estimated on the enhanced rental. Many speculators bought up such property and, anticipating its condemnation, raised the rents so as to secure higher compensation. This was not fair and means should be found to prevent such speculations.

Mr. FILDES, of the Manchester Sanitary Committee, complained that private enterprise was able to buy land cheaper than corporations, and Councillor PAGE of Plymouth showed that the rehousing scheme in his town could not be completed because the Government limited the borrowing powers of municipalities. He thought that the charge for the sinking fund might well be put on the rates as it was the means by which the community acquired valuable property.

Baillie W. F. ANDERSON said that for cheap dwellings they must have cheap land, and he could not understand why power was given to acquire land compulsorily at valuation so as to bury the dead and yet there was no similar power for housing the living. Then why should there be special powers to purchase insanitary property and no such powers to acquire unoccupied land?

Mr. TAYLOR, of the London County Council, thought that the freeholder should be made responsible for slum property. Freeholders often bought houses on their freeholds six or seven years before the termination of the leases. This was done on the pretext that the leaseholder could not afford to repair the dilapidations. But when the freeholder had thus obtained possession of the houses he did not repair them. On the contrary, he encouraged an increase of dilapidation in the hope that the dwellings would be condemned and that he would get a handsome compensation. Thus the London County Council had been obliged to pay as much as £100,000 per acre of land and the houses which they had erected cost £100 per inhabitant.

Some town councillors now asked if the discussion was to lead to any practical results and resolutions were promised for the following day. Dr. H. SCURFIELD (Sunderland) wanted to know whether or no anything whatsoever had been done at Glasgow or elsewhere to meet the most urgent phase of the question—namely, the housing of those whose earnings did not exceed £1 per week.

Councillor GRAY and Councillor BURT replied to the discussion and objected to Mr. McDonald's proposed shilling-a-week tenements. It was not a question of how miserably and

cheaply it was possible to lodge human beings. The cheaper the building the higher in proportion would be the cost of the land. They should strive for the higher ideal of good rather than cheap houses. The building described by Mr. McDonald might be fit for a dog-house; it was not worth while devoting their energies to the erection of such miserable dwellings for human beings. Better far strive to break the monopolies that held back the land.

In reply to Dr. SCURFIELD'S question the CHAIRMAN said that though many efforts had been made in Glasgow the fact that they had convened this conference proved that they were not satisfied with the result. They had not the necessary accommodation for those who earned less than £1 a week.

The Conference was then entertained at lunch by the Glasgow Corporation in the largest of the palatial salons that form part of the City Chambers.

(To be continued.)

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

### *Increase of the Plague Epidemic.—The Establishment of the Indian Medical Service.*

FOR the week ending Sept. 7th there has been an increase of nearly 1000 deaths from plague. In the Bombay Presidency the number of deaths has risen from 3243 to 4132, in Mysore from 336 to 377, and in Bombay city from 216 to 235. The districts chiefly affected on the Bombay side are the Kolhapur State and the district of Dharwar. The gradual development of the death-rate in Poona during the last few weeks has at last shown itself in the entry of several cases to hospital. It would, therefore, seem that Poona is once more threatened with an outbreak. The number of cases in Bombay city has been rising steadily for several weeks past. Elsewhere the disease seems quiescent, but the continuance of a few cases in Calcutta and the occurrence now and again of a case at Patna should warn the authorities that after the usual interval it may be expected to revive. The general mortality in Calcutta is for the present exceptionally low—something like 20 per 1000 per annum—while in Bombay city the death-rate is 61.11 per 1000. The mortality in the city of Madras still remains abnormally high, the returns for the week ending August 30th showing a rate of 114.3. In this city, however, the mean for the past 10 years is very high—viz., 57.6 per 1000. The deaths from cholera do not account for the excess mortality.

I hear that the Secretary of State will not concede all that the Government of India asked for. The Indian Medical Service is to be increased by 26 officers, not by 52. The demands on the service are still very great. Although famine has largely decreased and is not likely to recur there is no sign of the plague dying out. Medical officers will be required for plague duty and the native forces and hospitals in China must be provided for. The increase of the native army by five battalions means a still further drain on the Indian Medical Service. A still further increase in the establishment must come sooner or later.

Sept. 14th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *The New Anatomical Laboratory at University College, Liverpool.*

THE new anatomical building in connexion with University College has recently been completed. The ground-floor contains the anatomical museum, which includes a large variety of valuable specimens. This room is spacious and is surmounted by a mezzanine floor or gallery also containing anatomical specimens. The dissecting room occupies the first-floor and is one of the finest rooms imaginable. It is luxurious in appearance and is flooded with light. It is about 66 feet long by 36 feet wide, and is amply supplied with every appliance necessary for dissections. There are 12 slate tables and six wooden ones. The fixed basins, which are numerous, are supplied with hot and cold water. There is

also an electric air fan, the building being lighted throughout by electricity. Students of the present day may, indeed, congratulate themselves upon the fortunate circumstances attending their study of anatomy; the contrast between a dissecting-room on the lines of that recently opened at University College and the dissecting-room of 30 or 40 years ago is simply astounding. Professor A. M. Paterson is also to be congratulated upon being at the head of a laboratory which is one of the finest in the kingdom.

*The Liverpool Chamber of Commerce and the West African Sanitary Commission.*

A letter from the Colonial Office was read at the meeting of the Chamber of Commerce on Sept. 16th asking for the views of the committee respecting the selection of a scientific expert to accompany the West African Sanitary Commission. Also a letter from the London Chamber of Commerce was read suggesting that in view of the difficulties which have arisen separate mercantile delegates should be appointed to visit the different colonies. It was resolved to write to the Colonial Office saying that as the Liverpool School of Tropical Medicine has sent, and is sending, expeditions to several of the West African colonies the committee of the African trade section of the Liverpool Chamber of Commerce is of the opinion that the departure of the proposed commission should be delayed pending the receipt of reports to be furnished at an early date by the school as to the results of its most recent efforts.

*The Liverpool Water-supply.*

Happily, in Liverpool there is no dearth of the water-supply, as is just now experienced in Manchester. The water engineer reports that the total quantity of water supplied both within and without the compulsory limits for the week ending Sept. 14th was 204,704,000 gallons, an average of 29,243,000 gallons per day, as compared with a total output in the corresponding week of last year of 199,980,000 gallons, or an average of 28,568,000 gallons per day.

*Lunacy in the West Derby Union.*

The number of lunatics certified for removal to asylums is greater in the West Derby Union than in any union throughout the whole country. The clerk to the guardians had failed to find the reason for the large number of insane persons brought to their workhouse. The only supposition was that the West Derby Union offered greater facilities to the police for bringing in cases than were afforded by other unions; but in any case the numbers are appalling—viz., one in 373, as compared with one in 507 in the county, and one in 434 in England and Wales. An appeal was made to the medical men having seats on the board to try to discover if any means could be suggested for minimising this enormous drain on the resources of the union.

*North-Western Poor-law Conference.*

At the twenty-seventh annual meeting of the North-Western Poor-law Conference held at Chester on Sept. 20th the chairman (Sir J. T. Hibbert) made allusion to the increase in the number of lunatics throughout the country as well as in their own two counties of Lancashire and Cheshire. In many of their asylums they had a congestion of lunatics, many of whom might very well be moved out to make way for other cases. The asylums ought to be used for curative cases, whereas they had a large number of chronic lunatics, quite harmless, and who never would be better, occupying the places of those who needed active treatment and were curable. All four asylums in Lancashire were full to overflowing. He recommended that the Asylums Board should appoint a small committee of experts, if they could get them from their own body, and go through the four asylums and examine every lunatic there. He was bound to say that they would find hundreds who had no right or necessity to be there and who might just as well be treated in the workhouse. They had 8986 lunatics in their four Lancashire asylums and they had 2834 lunatics or imbeciles in their workhouses.

*Infectious Diseases Hospital for Preston.*

The Preston Town Council have arranged to erect an isolation hospital, with accommodation for from 60 to 70 patients, at a cost of about £30,000, with an annual cost of maintenance of from £2000 to £3000.

*Royal Albert Asylum: Opening of the Ashton Wing.*

The opening ceremony of the new Ashton Wing of the

Royal Albert Asylum, Lancaster, took place on Sept. 26th. The new wing, towards the general cost of which Lord Ashton has contributed £15,000, is about 150 feet long and two stories high, and will provide for the accommodation of 50 cripples on the ground-floor and 50 epileptic patients on the first-floor, which is level with the ground-floor of the main building. The plan is on the "pavilion" principle, and each floor consists of a large day room, 54 feet by 32 feet, at the end, with a smaller room opening out of the main room; two dormitories, one 60 feet in length and the other 41 feet in length and 27 feet wide, projecting at right angles from the main corridor; a stone staircase, lavatory, bathroom, and water-closets, &c., in separate blocks, with a disconnecting corridor. The total cost of the new wing was £20,117 11s. 7d. There was a large attendance of visitors, Sir J. T. Hibbert, K.C.B., chairman of the central committee, presiding over the proceedings. The chairman, in accepting the building, said that the northern counties had the highest appreciation of the noble generosity of Lord Ashton who had contributed so largely towards the costs of erection. His lordship had done many generous acts and he trusted that the memory of that day would not be among the least pleasant of his thoughts. He desired to convey the thanks of the committee to his lordship.

Oct. 2nd.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*Swansea Isolation Hospital.*

THE county borough of Swansea, which has a population of 94,000 persons, is very inadequately provided with isolation hospital accommodation. The Local Government Board has from time to time drawn the attention of the corporation to the necessity for very considerably increasing the accommodation in the existing hospital with its 20 beds, and more than three years ago the medical officer of health (Mr. Ebenezer Davies) reported in some detail on the subject. In that report Mr. Davies advised the erection of an administrative block, four ward pavilions with 12 beds in each, and an observation block containing four two-bed wards, giving a total accommodation for 56 patients. A site five and a half acres in extent belonging to the corporation has been suggested as suitable for the erection of these buildings, and it is anticipated that they will now be proceeded with. The experience of Swansea as regards small-pox outbreaks has been satisfactory, for it has been found possible to isolate, even with the existing meagre facilities, every case as it occurred. Quite otherwise has it been with scarlet fever, diphtheria, and typhoid fever; the proportion of admissions to hospital to cases in these diseases has been very small indeed. In the year 1900 the death-rate from diphtheria in Swansea was 0.64 per 1000, a rate only exceeded in two of the 33 great towns, Leicester and Sheffield.

*Colliery Surgeons.*

Speaking generally, the colliery surgeons in the Glamorgan-shire coal fields are remunerated by a fixed sum per pound, usually 3d., being deducted from the wages of the men employed at the particular colliery concerned. For this sum the surgeon provides everything required in the conduct of his practice. In Monmouthshire, although a poundage is deducted from the colliers' earnings, a committee receives the amount and pays therefrom all the expenses of the practice, such as assistants, drugs, horse hire, and a fixed sum is given to the surgeon. So long as the men are regularly employed this system works well, but when a strike takes place or for some other reason employment is intermittent, the "doctor's fund" is rapidly depleted. Such a condition has actually occurred at Blaenavon, where one principal surgeon, two assistants, and a dispenser are engaged by the committee, and where there is a dispute pending between the colliers and the masters. The men employed at a certain set of collieries in the Rhondda Valley have decided by a ballot to adopt the Monmouthshire system, and instead of paying as they have hitherto done a threepenny poundage direct to the colliery surgeon this sum will be paid over to a committee, who propose to pay a surgeon at the rate of £416 per annum, to provide him with a house and a horse and carriage, to pay for drugs and incidental expenses, and also to engage a dispenser and a nurse. This is not the first colliery in the Rhondda valleys to adopt the

committee system, for nearly three years ago the colliers employed at Ferndale were able to choose between paying a poundage to Mr. T. W. Parry, who has been surgeon to the colliery since the first pits were sunk 20 years ago, or paying a levy in support of the surgeon engaged by a committee of the workmen. In this case the majority of the men are attended by Mr. Parry.

#### *Public Health Questions at Cardiff.*

In his report for the second quarter of the year the medical officer of health of Cardiff (Dr. E. Walford) states that during the three months under review eight vessels entered the port from plague-infected and plague-suspected ports and that he examined 281 persons with negative results. About 325 rats were caught and destroyed during the same period upon vessels from infected ports. In an additional report upon the British Congress on Tuberculosis Dr. Walford states that he considers that sanitary authorities are not justified in relaxing their efforts to prevent the sale of tuberculous meat and milk, and that he will still continue the practice of condemning the entire carcass of an animal which has suffered from generalised tuberculosis and of the portion affected where the disease is localised.

#### *Meat Inspection at Swansea.*

The Swansea Butchers' Association desire that the corporation meat inspector, who is a qualified veterinary surgeon, shall be instructed to permit the owners of meat which he has seized to call in expert opinion upon their behalf. The corporation have very properly declined to limit the discretion of their inspector, who, it appears, invariably complies with any request for such an opinion.

#### *Bristol Royal Infirmary.*

The half-yearly meeting of the governors of the Bristol Royal Infirmary was held on Sept. 24th under the presidency of the Dean of Bristol. The report stated that for the first six months of 1901 there had been 1495 in-patients admitted, an increase of 23 compared with 1900. The out-patients numbered 15,803, compared with 15,745 for the corresponding period of last year. 286 patients had been sent to the Royal Victoria Convalescent Home. The financial statement showed that during the half-year the expenditure amounted to £7558, as against £7736 for the first six months of 1900. The chairman stated that it had been decided to form a distinct bacteriological and pathological department at the infirmary and that the drainage of the institution was being improved.

Sept. 30th.

### SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Resignation of Dr. D. Yellowlees.*

DR. DAVID YELLOWLEES, who has for 27 years been physician-superintendent of the Glasgow Royal Asylum for Lunatics, has signified his resignation to the committee of management. The regret caused by this position is heightened by the knowledge that this step has been forced upon Dr. Yellowlees by failing eyesight, and every good wish for restored health will follow him into his retirement. In addition to his special work in connexion with the management and treatment of the insane Dr. Yellowlees has for many years been lecturer on insanity in the University of Glasgow, a position which he has filled with great distinction. Quite recently he was for three successive years elected President of the Faculty of Physicians and Surgeons of Glasgow. He has also largely interested himself in various social and philanthropic movements, and his retreat into private life will cause a gap in many local organisations. The committee of the asylum have appointed him honorary consulting physician and have placed on the minutes an appropriate expression of their sense of the value of his services and a resolution of regret at his resignation. The appointment is worth £1000 per annum with a free house at the institution.

#### *The Prevention of Consumption.*

As a result of the public meeting held in Glasgow in March last a local branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis has been formed in Glasgow. The Duke of Argyll has consented to act as patron and the Lord Provost as president. The

vice-presidents include the Duke of Hamilton, the Duke of Montrose, the Earl of Home, Lord Blythswood, Lord Kelvin, and Lord Inverclyde. The executive council, consisting of a number of representative citizens presided over by the Lord Provost, have issued an appeal for public support. Admission to membership is to be obtained on payment of a small subscription. The honorary treasurer is Mr. Robert Gourlay, LL.D.

#### *Lunacy in Scotland.*

The annual report of the Commissioners in Lunacy for Scotland states that during 1900 the number of insane persons was increased by 246 as compared with the year 1899. Of the 15,899 certified lunatics, 2395 are maintained from private sources, 13,458 by parochial rates, and 46 at the expense of the State. It also appears from the report that 21 per cent. of the patients who had been liberated on probation since 1862 had been replaced before the close of the period of probation in the asylum from which they had been liberated.

#### *The Carnegie Trust.*

A meeting of the Carnegie Trust was held on Sept. 30th. A number of applications from students for the payment of class fees were dealt with, and it is expected that the decision of the Trust will be communicated to the applicants in the course of the next fortnight. In view of the fact that this is the first year in which the Trust has been instituted, and that a certain number of students may therefore have failed to observe the date fixed by the committee for the reception of applications, it was decided to extend the time to Oct. 15th, when the list will be finally closed for the winter session. Mr. Carnegie has indicated his readiness to assist yet another educational institution—namely, the Glasgow and West of Scotland Technical College. The estimate for rebuilding this was placed at £150,000, towards which £100,000 have been subscribed. Mr. Carnegie is willing to give one-half of the deficiency upon condition that the other half is promptly raised.

#### *The Water-Supply of Glasgow.*

A handsome volume giving a complete historical account of this subject has just been completed by Sir James D. Marwick, LL.D. It provides a graphic and continuous narrative of the means adopted to obtain a water-supply for the city from the earliest period of record. Naturally the most interesting part is that dealing with the provision of water from Loch Katrine. The works in connexion with this supply were commenced in 1856 and completed in 1859 at a cost of nearly £1,000,000. The book contains useful maps showing the positions of the reservoirs, lines of aqueducts, and so on.

Oct. 1st.

### IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Commencement of the Medical Session in Dublin.*

ON Oct. 1st work was commenced in all the medical schools and clinical hospitals of Dublin. The Royal College of Surgeons in Ireland has announced the opening of its school and of its preliminary examinations. The autumn examinations of the Royal University of Ireland are in progress. At the Meath Hospital and County Dublin Infirmary (one of the oldest clinical hospitals in Ireland) Mr. William Taylor will deliver the inaugural address on Oct. 14th, thus formally beginning the session there. At the Mater Misericordiae Hospital, which is much the largest clinical hospital in Ireland, the junior classes met for clinical lectures on Oct. 1st. The medical board of St. Vincent's Hospital have also just issued invitations for the address introductory to the medical session to be delivered by Dr. M. F. Cox on Oct. 8th. Sir Christopher Nixon of the Mater Misericordiae Hospital and Dr. Cox of St. Vincent's Hospital are both senators of the Royal University of Ireland and have recently given evidence at the meeting of the Royal Commission.

#### *Armagh Guardians and the Local Government Board.*

ON Sept. 9th the Armagh Guardians passed a resolution to the effect that in their opinion certain remarks made by the Local Government Board inspector, Mr. Agnew, about Mr. R. T. Heron, medical officer of the board, were uncalled for, and that the inference drawn by the Local Government Board from his remarks was unjust, and calling on the Local Government Board to withdraw the portion of the

letter referring to Mr. Heron. In reply to this a letter was read from the central authority in Dublin at a meeting of the Armagh Guardians on Sept. 24th, stating that Mr. Heron's attendances at the workhouse, as shown for a long time by the inspector's reports, had not been in accordance with the workhouse rules, and finding fault with the dietary of nursing mothers and infants and pointing out that the order to diet them according to their individual requirements had a wider significance than that given to it by the medical officer. After this communication was read a resolution was unanimously passed by the guardians stating that it was not in their opinion a satisfactory reply to their resolution and calling upon the Local Government Board to withdraw the unjust censure of their medical officer.

*The Proposed New Board-room for the Belfast Guardians.*

The Local Government Board have sent a letter to the Belfast Guardians, which was read at their meeting on Sept. 24th, adhering to their decision to refuse to sanction the expenditure of a sum of £13,500 on a board-room and offices as being an unprecedented sum in their experience. An amusing bit of fun is poked at the guardians in this letter by the Local Government Board stating that "the cubic capacity of the proposed board-room for the accommodation of 60 guardians is said to be about equal to that of the House of Commons at Westminster, and the furniture and fittings for the board-room were to be provided at an estimated cost of £700." After an animated scene it was decided to hold over the letter for a week.

*The Registrarship of Queen's College, Belfast.*

The Registrarship of Queen's College, Belfast, is now vacant through the resignation of Professor J. Purser. The appointment is worth £75 per annum with a college residence (coal and gas included). The Lord Lieutenant has intimated that he is prepared to consider any application for the office that may be submitted by professors of the College who desire to become candidates for the position. Up to the time of the appointment of Professor Purser the post was held by an official who was not a professor.

*The Royal Commission on Irish University Education.*

The first session of the Royal Commission on Irish University Education terminated on Sept. 28th. A great many witnesses (23) have already been examined and the minutes of evidence in the official report will, it is said, be available for the public in a few weeks. It has been arranged that the next session of the Commission will not take place until this volume of evidence has been published and adequate time has elapsed for its consideration. The Commission will probably meet again in Dublin towards the end of November for the consideration of matters relating to technical education. They will sit in London on Dec. 17th for a few days and afterwards in Ireland, at places and times not yet fixed, but probably beginning in Belfast after Christmas. Exception is still very strongly taken by the Irish press to the proceedings of the Commission being held in private on the ground that the evidence is practically buried and that not one in a thousand of those who would have read it with interest in the daily newspapers will now ever have a chance of perusing it. There is such diversity of opinion on the education question in Ireland that the public are entitled to know what is going on in the matter. Had the Commission been composed, as is usually the case, of unbiased experts publicity might not have been necessary, but this is not the case in the present extraordinarily-constituted body, and hence the very great importance of removing the suspicion which not only exists but which has become intensified, and of allowing the "man in the street" to know what is going on. The proceedings at the 1884 Commission on the Queen's Colleges and at the Intermediate Education Commission were both conducted in public.

Oct. 1st.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*The Association Tonkinoise.*

A VERY interesting medical charity has been at work in France for about 12 years. It is little known, however, even in France, but owing to an article recently published in the *Presse Médicale* the nature of the services

which this association renders has been made public. Its special work is to provide convalescent homes to colonial soldiers who have returned to France feeble and in ill-health after their term of service has expired. It was founded in 1888, under the name of the *Association Tonkinoise*, with the original object of uniting in a friendly association the veterans of the Indo-China War, but to-day its action extends throughout all the military colonies. A hospital of 50 beds has been founded at Nancy, destined especially for the inhabitants of Alsace-Lorraine, who, having deserted their province owing to its having become German, with the intention of entering the French army, find themselves on leaving their regiment in ill-health and out of work. From this hospital they go out relieved and provided with a situation. At Paris the association has founded an institution containing 25 beds, together with a refectory, and since 1892, when this hospital was opened, some 10,000 men have passed through it, with a mean stay in the hospital of five days. At Bordeaux and at Marseilles and in the other chief seaports local committees have been organised who look after sick colonial soldiers and see that they are duly helped. The headquarters of the society, however, is the large convalescent institution at Sèvres. This is an old eighteenth-century chateau which formerly belonged to the Marquise de Pompadour. It is in a beautiful situation on the banks of the Seine, standing in a large park and commanding a view of Paris. It was handed over to the society by Madame Fürtado Heine. Discharged colonial soldiers who have returned suffering from anæmia or the various fevers may stop here without any expense to themselves for one or two months. Convalescent colonial soldiers who have not completed their term of regimental service are also received, supposing, that is, that they have no family or home to go to during the time of their convalescence. Civilian explorers are also received provided that they have no means upon their return to France. The house is in thorough sanitary condition, is well lighted and ventilated, is kept beautifully clean, and its hygienic condition is constantly kept in perfection. The régime of the house is almost military, and everybody upon his arrival is allotted a position in conformity with his military grade. Everybody is in uniform; everybody must work. Private soldiers are put to manual labour and non-commissioned officers do clerks' or overseers' work. When the new chair of Colonial Pathology, together with its special hospital service in Paris, shall have been put into working order this hospital at Sèvres will be attached to the chair as a convalescent hospital, and in this way there will be a very complete medical organisation for colonial soldiers who have returned to France in ill-health.

*Official Instructions with regard to the Fight against Tuberculosis.*

The Ministers in charge of various Government departments have begun their fight against tuberculosis and various instructions have already been published. The Minister of War, acting upon a report of the Technical Committee of Health, has just issued instructions that zinc spittoons should be placed in all the barracks in the proportion of two spittoons to each room, while an extra large one is to be placed on every landing of the staircase. Sentry-boxes are also to be provided with them and every regiment has to procure these spittoons at its own expense. The Minister of Public Works has issued a circular to the railway companies in regard to cases of tuberculosis among the employés which is the complement of those already sent out in reference to the hygiene of railway carriages and railway stations. The railway companies are required to submit every person applying for a post on their staff to a very rigorous medical examination, and anyone who is suspected of tuberculosis, or who even appears likely to contract the disease, is not to be admitted to the staff. Those who are attacked with tuberculosis after being taken in the service of the company must, if their cases be slight, be given a change of work. For instance, railway servants employed in offices shall be given some work which will occupy them in the open air. The Minister does not recommend the companies to build special sanatoria, for, as he says, their usefulness has not been absolutely demonstrated so far.

*The War against Mosquitoes.*

The Council of Hygiene and Public Health of the Department of the Seine in pursuance of a resolution passed by the Academy of Medicine with reference to a study of the means

for destroying mosquitoes in Paris has recommended the following precautions to be taken :—

1. All drains and gully-pipes, especially those in the street as well as those in Paris houses, must be carefully inspected so as to avoid any stagnation of their contents. Pipes should be inspected week by week and any collection of insects destroyed either by fire or else by being well swept out with lime.
2. All latrines and water-closets should be kept strictly clean and no collection of insects of any kind whatever should be allowed to remain therein.
3. Collections of standing water in gardens and courtyards should by no means be permitted, and this regulation must be strictly observed in places where men are collected together, such as hospitals, prisons, barracks, and the like.
4. All collections of water, such as fountains, together with their basins, in public streets should be carefully emptied and cleaned at least once a week. In connexion with water of greater size, such as lakes and ponds, as many fish as possible should be kept.
5. Water-tanks and cisterns in private houses should be treated as follows: one gramme of petroleum should be used for every square superficial metre of water, or, if the water is to be used for drinking purposes, olive oil should be used in the same quantities.
6. In quarters known to be infested with mosquitoes the inhabitants are especially recommended to use a mosquito-net.
7. With regard to mosquito bites, the best thing to apply is a drop of tincture of iodine or a drop of a 1 per cent. solution of guaiacol.

With reference to the subject of mosquitoes and malaria Médecin-Major Billet has laid before the Academy of Science a very interesting paper in confirmation and explanation of the fact already reported by Monsieur Laveran that in Algeria, and particularly in the province of Constantine, cases of malaria which occurred in patients hitherto unaffected are always noticed in the latter days of the month of June, thus coinciding with the appearance of mosquitoes belonging to the anopheles species which are looked upon as the principal agents in spreading the hæmatozoa of malaria. Monsieur Billet noticed that the mosquitoes began to appear between June 15th and 21st, and on examining them he found in their stomachs malarial sporozoa. Between June 26th and July 1st the military Hospital at Constantine received patients suffering from malaria who came from barracks in the exact locality where the mosquitoes had appeared. All the cases were, without exception, cases of malaria in patients who had never had it before—that is to say, they were young soldiers recently come from France who had entered the army in the month of November, 1900, and in addition in all of them examination of the blood revealed the presence of hæmatozoa peculiar to a first attack of malaria.

(FROM OUR OWN CORRESPONDENT.)

### *Bubonic Plague at Naples.*

THAT Naples should for so long have escaped a visitation of the plague is a matter for some surprise when it is remembered how constant and extensive is its intercourse with the infected ports of Egypt and the East. That this immunity was due more to good fortune than to the vigilance of the authorities has been freely suspected and now appears to be confirmed by the report that cases of so-called adenitis have existed at Punto Franco and have been treated in the neighbouring hospitals since, at any rate, the end of August. It was not, however, till the morning of Sept. 23rd that the authorities were notified of these suspicious cases and of the fact that a great mortality was occurring amongst the rats in the port. The provincial medical officer of health was at once despatched to investigate and to take the necessary precautions. A number, not yet definitely declared but said to be about a dozen, of cases are reported to have already shown themselves amongst the labourers engaged in unloading cargoes at the docks. Some weeks ago one of these men had gone to the Pellegrini Hospital on account of a swollen inguinal gland. The medical officer on duty failed to diagnose its nature and treated the ailment as a simple adenitis. Nor did the death of the patient, which occurred a few days later and was ascribed to strangulated hernia, rouse any suspicion of plague. Some days afterwards another labourer complaining of similar symptoms was admitted at the Incurabili Hospital, where he too died, as was supposed at the time, from typhlitis and perityphlitis. These facts and others of a similar kind, together with the large mortality amongst the rats, came accidentally to the knowledge of Dr. Sorge, surgeon to the Società dei Magazzini, who immediately reported them to the prefect of

the city. The bacteriological examination of material both from the patients and from the rats leaves no doubt of the disease being plague. The exact origin of the outbreak will now be very hard, if not impossible, to determine, and the adoption of efficient prophylactic measures will be correspondingly difficult. The sewers of Punto Franco are independent of those of the city, and it is hoped that this may enable the authorities, by destroying all the rats in them, to prevent an extension of the disease by means of these rodents. But, unfortunately, the labourers who have presumably come in contact with the infection are only partly resident in Naples, the greater number being unattached and coming and going frequently according to the amount of work to be done. It is thus possible that the infection has already been carried by these latter to other localities. Meanwhile, all those known to have had contact with plague patients have been isolated and the patients themselves, together with their families, have been conveyed to the lazaretto of Nisido. Their houses are being disinfected and all their clothing, &c., destroyed. All work is suspended at the warehouses and the formidable task of disinfecting the vast stores of merchandise accumulated there has been begun. The Government has ordered large supplies of Yersin's serum from the Pasteur Institute in Paris and of Haffkine's serum from the State Laboratory in the island of Panosa. The energetic steps being taken by the authorities, as well as the generally satisfactory sanitary state of Naples itself, tend to allay the alarm felt at this outbreak of a disease which in past times has so often proved such a deadly scourge amongst the population of Italy. Should the infection unfortunately spread to surrounding towns less favoured in their sanitary conditions the outlook will be much more serious, sunk as so many of their inhabitants still are in ignorance and superstition and with ideas of personal cleanliness and public hygiene little more advanced than when in the Middle Ages the Black Death raged amongst them and swept them away by thousands. Elaborate precautions are being taken at Rome to prevent the importation of the disease into the capital, while at Palermo, Genoa, and other places in close communication with Naples the sanitary authorities are actively bestirring themselves, spurred on, not only by the danger to the public health which such an invasion would carry with it, but also by a knowledge of the grave financial consequences which it would certainly produce at this the commencement of the Italian tourist season.

Sept. 27th.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *Some Features in the Case of the late President McKinley.*

SINCE four o'clock of the afternoon of Friday, Sept. 6th, when the news was flashed through the country that President McKinley had been shot down by the hand of an assassin at the Buffalo Exposition, the appalling crime has been the one absorbing topic of interest. President McKinley at the time of the shooting was receiving the people in the Temple of Music at the Pan-American Exposition. The crowd was passing in front of him in single file and he was shaking hands with each member in turn when a man appeared who had his right hand, apparently injured, held up to his breast, with a handkerchief arranged in such a manner as to create the impression that it was bandaged. Upon arriving opposite to the President, whose hand was extended, the miscreant fired two shots from a pistol concealed by the handkerchief, wounding the President in two places. The automobile ambulance attached to the emergency hospital was quickly on the spot and the injured President was conveyed with all possible celerity to that institution, arriving at 4.14 P.M. The principal surgeons of Buffalo were sent for, as well as Dr. Rixey, the President's personal medical attendant. At five o'clock, an hour after the occurrence, Dr. Matthew D. Mann arrived, closely followed by Dr. Mynter and Dr. Parmenter. At 5.30 P.M. Dr. Rixey arrived and without further delay the operation was commenced by Dr. Mann, assisted by Dr. Mynter, Dr. Parmenter, and Dr. Lee. One bullet, it was found, had occasioned but slight injury; it had struck the sternum, producing a simple contusion. The other had gone through the abdomen five inches below the nipple and one and a half inches to the left of the median line. The abdomen was opened by an

incision including the point of entrance of the bullet, when it was discovered that the anterior and posterior walls of the stomach had been penetrated. The holes were closed by silk sutures. Further examination failed to disclose that other important organs had been injured, nor could the course of the bullet be traced beyond the posterior wall of the stomach. The bullet was not found. Towards the end of the operation Dr. Roswell Park, who had been at Niagara Falls, arrived upon the scene. The President, who had stood the anæsthetic and operation well, was removed from the hospital to the house of Mr. Milburn. The progress of the distinguished patient, judging from the bulletins given out by the medical attendants, was for four days remarkable; so much so, indeed, that the surgeons who performed, and were present at, the operation, together with Dr. McBurney of New York, who had been called in as consultant, declared it to be their opinion that recovery might be sanguinely anticipated. Throughout the case the bulletins were exceptionally hopeful and cheering, and the American public had begun to regard a favourable result as certain when alarm was spread by the news that a second slight operation had been deemed necessary. This was, however, explained away as being of no serious nature, and again the reports pointed to a successful issue. On the morning of Friday, Sept. 13th, this hopeful outlook was wholly altered, and ominous misgivings were created by the news that the President had experienced a severe attack of heart failure in the night, almost amounting to collapse. From that time until his death, which occurred at 2.15 A.M. on Saturday, Sept. 14th, he sank gradually, the latter few hours of his life being passed in a state of unconsciousness. The symptoms of heart failure were, it is said, attributed by the medical men in attendance on the President not directly to the wounds but to the fact that the heart was in that condition known as tobacco heart. Consequently the result of the necropsy was eagerly awaited by the American medical profession. The necropsy—which was made on Saturday, Sept. 14th, nine hours after death—was performed by Dr. Harvey D. Gaylord, and Dr. Herman G. Matzinger of the New York State Laboratory. There were also present Dr. McBurney and Dr. Edward G. Janeway of New York, W. P. Kendall (Surgeon, United States Army), Edward L. Munson (Assistant Surgeon, United States Army), Dr. W. W. Johnson of Washington, Dr. Charles Cary, and Dr. Hermanns L. Baer, in addition to the surgeons who were in attendance throughout the case. The official report of the necropsy is as follows:—

The bullet which struck over the breastbone did not pass through the skin and did little harm. The other bullet passed through both walls of the stomach near its lower border. Both holes were found to be perfectly closed by the stitches, but the tissue around each hole had become gangrenous. After passing the stomach the bullet passed into the back walls of the abdomen, hitting and tearing the upper end of the kidney. This portion of the bullet-track was also gangrenous, the gangrene involving the pancreas. The bullet has not yet been found. There was no sign of peritonitis or disease of other organs. The heart walls were very thin. There was no evidence of any attempt to repair by nature and death resulted from the gangrene which affected the stomach around the bullet wounds as well as the tissues around the further course of the bullet. Death was unavoidable by any surgical or medical treatment and was the direct result of the bullet wound.

It is conceded on all sides that the operation performed by Dr. Mann was both proper and brilliant. Nevertheless, the findings of the necropsy have revealed the truth that it did not go far enough. That the illustrious sufferer's life could not in any event have been saved the results of the necropsy show, and probably time was too valuable to be spent in a longer examination, but there would seem to be no doubt that the surgeons who performed and assisted in the operation were unaware of the injury to the kidney. The optimistic tone of the bulletins is a proof that the surgeons were sanguine of a favourable termination, though considerable comment was caused by the failure to locate the bullet. The cause of the gangrene along the entire bullet-track is also a matter which is arousing much discussion in medical circles. That the bullet was poisoned is a theory which has been mooted in many quarters, and, as might be expected, the notorious yellow journals have seized upon this suggestion with ghastly avidity. The likelihood, according to others, is that the bullet having been fired from a pistol of small penetrating power, the missile may have carried with it infection from the President's clothing, the germs of which had the opportunity of finding a nidus owing to the comparatively small velocity of the bullet. However, the publication of the further official reports of the necropsy may

clear up this point. It is worthy of note that the temperature of the patient was never very high, a fraction above 102° F. being the highest mark reached, but, on the other hand, the pulse was always rapid, while the respiration too was quick. The official reports of the surgeons in attendance on the President will be published in the principal medical journals of the country. It may be said that one New York paper has persistently given out that grave disagreement existed between the surgeons who attended President McKinley. So outrageous did its assertions to this effect become that the surgeons in question were compelled in self-defence to issue a contradictory statement, declaring that a very unusual harmony of opinion and action prevailed among them all through the case. Pending the completion and publication of the official reports of the post-mortem examiners no further statements for publication will be made by them.

#### *Seasonal Variations in the Growth of Boys.*

Some interesting observations have been made in an institution in Boston on the variations in the growth of boys between the ages of seven and 14 years. Once each week all the children were stripped and weighed, and their heights were measured every three months, except in the third quarter, which occurred in holiday time. 20 out of 30 boys remained in the home during the year, and these only are considered in the report. 1. Variations in weight amounting in some cases to as much as five pounds were observed in the boys, for the most part, from week to week. These variations were so numerous that it was suggested that any single test of an individual is liable to a plus or minus error of several pounds, and that successive weighings are necessary for accuracy. 2. Over 90 per cent. of the total increase in weight occurred during the period from June to December. 3. The fluctuations in weight were much more marked during the period of minimum growth, which seemed to indicate that there was less resistance to external influences during this time and that on the whole the vitality of the child was at a lower level. 4. A preliminary study of the weather conditions in connexion with these curves of growth showed that rainfall, temperature, and barometric pressure had slight, if any, influence. Humidity, on the other hand, seems to have had some influence during the period of minimum growth. 5. The general form of the curve of growth in weight was found common to all individuals studied, covering the ages from seven to 14 years. The larger minor fluctuations were found to be common to the majority of the boys, suggesting that the causes were general rather than individual, and that growth throughout this age-period has the same general seasonal variation. 6. Growth in height in the majority of cases showed either a continuous increase at the same rate throughout the year or more rapid growth during the period of most rapid increase in weight.

#### *Malaria a Notifiable Disease.*

The New York City Board of Health has adopted resolutions to the effect that the officers of "public institutions, hospitals, homes, asylums, &c., be required to report all cases of malarial fever which come under their observation, giving the name, age, sex, occupation, and present address of the patient," and "also information as to whether the attack is a primary infection or a relapse, and the address where the disease was probably contracted"; also "that all physicians in the city of New York be requested to furnish similar information in regard to patients suffering from malarial fever under their care."

Sept. 23rd.

UNIVERSITY COLLEGE, BRISTOL.—The session 1901-2 will commence on Oct. 8th, when the inaugural address will be delivered by the Bishop of Bristol on "The Responsibilities of Inheritance."

HOSPITAL SATURDAY FUND: ST. JOHN AMBULANCE CLASSES.—Classes in first aid to the injured for men and women under the tuition of the honorary surgeons of the St. John Ambulance Association will be held at the offices of the Fund, 54, Gray's-inn-road, London, W.C., on Wednesday and Saturday afternoons. The first-aid class for men has commenced already. The first-aid class for women will commence on Oct. 12th, a lecture being delivered at 4 P.M. Instruction in bandaging, &c., will be given at 5 P.M. After Christmas nursing classes will be held for men and for women.

## Medical News.

**UNIVERSITY OF DURHAM.**—In the Faculty of Medicine the following candidates have been successful in the third examination for the degree of Bachelor in Medicine under the new regulations:—

*Second-class Honours.*—Chella Mary Hankin, London School of Medicine for Women, and Arthur Gibson Dunn and Charles Harold Crass, College of Medicine, Newcastle-upon-Tyne.

*Pass List.*—Thomas Engelhart Amyot and Robert Story Brown, College of Medicine, Newcastle-upon-Tyne; Annie Tombleson Brunyate, London School of Medicine for Women; Ambrose Harold Bateman, William Morton Emmerson, and Francis Jollie Gowans, College of Medicine, Newcastle-upon-Tyne; Bryden Glendinning, Guy's Hospital; James William Gibson, Daniel Richard Guns, William George Thomas Hepplewhite, and Lizzie Evelyn Kendal, College of Medicine, Newcastle-upon-Tyne; Flora Murray, London School of Medicine for Women; Thomasina Georgina Prosser, Briton Smallman Robson, and Joseph Collingwood Stewart, College of Medicine, Newcastle-upon-Tyne; Marmaduke Cordeaux Wetherell, Guy's Hospital; and Auburn Lawrence Wilkinson and John Robert Wylie, College of Medicine, Newcastle-upon-Tyne.

**FOREIGN UNIVERSITY INTELLIGENCE.**—*Berlin*: Dr. J. Friedenthal has been recognised as *privat-docent* of Physiology.—*Breslau*: Dr. R. Sticher has been recognised as *privat-docent* of Midwifery and Gynaecology.—*Chicago* (*College of Physicians and Surgeons*): Dr. L. Blake Baldwin has been appointed to the Chair of Dermatology.—*Copenhagen*: Dr. Pontoppidan has been appointed to succeed the late Dr. Gædeken in the chair of Forensic Medicine and Hygiene.—*Cracow*: Dr. Chlumsky has been recognised as *privat-docent* of Surgery.—*Florence*: Dr. Pietro Imbriaco has been recognised as *privat-docent* of Operative Medicine.—*Freiburg*: Dr. Axenfeld of Rostock has been appointed Professor of Ophthalmology in succession to Dr. Manz, resigned.—*Göttingen*: Dr. W. Weber has been recognised as *privat-docent* of Psychiatry.—*Groningen*: Dr. Hamburger of Utrecht has been appointed Professor of Physiology in succession to Dr. Huizinga, resigned.—*Halle*: Dr. Ernst Ziemke has been appointed Extraordinary Professor of Forensic Medicine.—*Heidelberg*: Dr. Brauer has been appointed Extraordinary Professor of Medicine, Dr. Ferdinand Petersen Extraordinary Professor of Surgery, and Dr. Siegfried Bettmann Extraordinary Professor of Dermatology.—Dr. Julius Hegener has been recognised as *privat-docent* of Otolaryngology, and Dr. Martin Jacoby as *privat-docent* of Pharmacology.—*Iurieff* (*Dorpat*): Dr. Blauberg has been recognised as *privat-docent* of Toxicology.—*Jena*: Dr. Grober has been recognised as *privat-docent* of Internal Medicine, and Dr. Hans Berger has been recognised as *privat-docent* of Psychiatry.—*Leipsic*: Dr. H. Füh has been recognised as *privat-docent* of Gynaecology; a new pathological institute, which will include a department for forensic medicine, is to be erected in the Liebig Strasse.—*Leyden*: Dr. van Walsam has been appointed Professor of Pathological Anatomy in succession to the late Dr. Siegenbeek van Heukelom.—*Lund*: Dr. M. J. C. A. Forsman, Lecturer on General Pathology, has been appointed Extraordinary Professor.—*Munich*: Dr. Albert Jodlbauer has been recognised as *privat-docent* of Medical Pathology.—*Naples*: Dr. A. Cantani has been recognised as *privat-docent* of Medical Pathology, Dr. S. del Vecchio as *privat-docent* of Surgery, Dr. Lorenzo Mandalari as *privat-docent* of Psychiatry, and Dr. Antonio Reale as *privat-docent* of Dermatology.—*Padua*: Dr. Giuseppe Iona and Dr. Alberto Luzzatto have been recognised as *privat-docenten* of Medical Pathology and Dr. Cesare Merletti as *privat-docent* of Midwifery and Gynaecology.—*Pennsylvania*: Dr. Thomas R. Neilson has been appointed Assistant Professor of Genito-Urinary Diseases.—*Pisa*: Dr. E. Benvenuti has been recognised as *privat-docent* of Medical Pathology.—*Prague* (*German University*): Dr. O. Pittl has been recognised as *privat-docent* of Otolaryngology.—*Prague* (*Bohemian University*): Dr. Karl Weigner has been recognised as *privat-docent* of Anatomy, and Dr. R. Jedlicka as *privat-docent* of Surgery.—*Rome*: Dr. A. Marracino of Naples has been recognised as *privat-docent* of Medical Pathology; Dr. Tito Guadi has been recognised as *privat-docent* of Experimental Hygiene.—*Rostock*: Dr. Peters of Bonn has been offered the chair of Ophthalmology; Dr. W. Müller of Aix-la-Chapelle has been appointed Professor of Surgery in succession to Dr. Graser.—*Stockholm*: Dr. Johan Erik Johansson has been appointed Professor of Physiology.—*Strasbourg*: Dr. F. Weidenreich has been recognised as

*privat-docent* of Anatomy.—*Turin*: Dr. Calvini has been recognised as *privat-docent* of Surgery.—*Vienna*: Dr. Friedrich von Sölder has been recognised as *privat-docent* of Neurology and Psychiatry. Dr. H. Joseph has been appointed Lecturer on Zoology and Comparative Anatomy and Dr. Guido von Török as Lecturer in Surgery.—*Würzburg*: Dr. Jacob Riedinger has been recognised as *privat-docent* of Surgery and Dr. Paul Römer as *privat-docent* of Ophthalmology.—*Zürich*: Dr. Max Cloëtta, *privat-docent* of Pharmacology, has been promoted to an Extraordinary Professorship.

### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

The deaths of the following eminent foreign medical men are announced:—Dr. J. A. Winter, Extraordinary Professor of Pharmacology in Leipzig and editor of the Schmidt's Jahrbücher.—Dr. I. Salas, Professor of Physiology in San Luis, Potosi.—Dr. Sharginyan, *privat-docent* of Gynaecology in the University of Moscow, aged 42 years.—Dr. Th. M. Markoe, formerly Professor of Surgery in the College of Physicians and Surgeons, New York.—Dr. Vaucher, formerly Professor of Midwifery in Geneva.

**SACCHARIN IN BEER.**—A firm of brewers were summoned before the Coventry City Petty Sessions on Sept. 11th for using coal-tar saccharin in the manufacture of beer, a practice which was contrary to the Inland Revenue Act, 1888, and was prohibited by a notice published in the *London Gazette*. The proportion of saccharin contained in separate samples of beer collected in the defendants' brewery last May was respectively 1.10 grains, 0.89 grain, and 1.40 grains per gallon. It was estimated that the loss to the Revenue from the use of saccharin by the defendants was about £1000 per annum. Penalties amounting to £90 were imposed, together with £14 8s. costs.

**CONGRESS OF CRIMINAL ANTHROPOLOGY.**—The Fifth International Congress of Criminal Anthropology was opened at Amsterdam on Sept. 9th with an address by M. Van Hamel, the President. Mr. Havelock Ellis, the English delegate, and Mr. Clark Bell of New York were appointed vice-presidents. Professor Lombroso read papers on Degeneration, the Practice of Tattooing by Criminals, and the Remedial Possibilities of Symbiosis. Dr. Piepers read a paper on the Idea of Crime. M. Scipio Sighele of Brussels delivered an address on Collective Crime. He considered that the individuals composing crowds were not always responsible for their acts. On Sept. 10th the proceedings consisted mostly of a discussion on Degeneration and Criminality, the speakers including M. Winkler of Amsterdam, Dr. Garnier of Paris, and Signor Ferri of Rome. The afternoon sitting was presided over by M. Drill, counsellor to the Minister of Justice in St. Petersburg, and the subject of discussion was Juvenile Delinquency. Dr. Garnier of Paris said that offences committed by children, especially murder, were due to the abuse of alcohol by their ancestors, and expressed the hope that States would take measures against the abuse of alcohol. In the evening the members of the Congress were the guests of the students of the University. On Sept. 11th the morning sitting was presided over by Colonel McHardy, Chairman of the Prison Commissioners for Scotland. Signor Ferri read a paper on the Prevention and Repression of Crime and on the Symbiosis of Crime, or the utilisation of the energies of criminals in such a way that least harm was done to the community at large. Part of the day was devoted to a visit to the lunatic asylum at Meerenberg, near Haarlem. On Sept. 12th M. Drill of St. Petersburg spoke upon the responsibility of criminals. He contended that there existed neither a criminal type nor a born criminal, and was of opinion that crime could best be prevented by schools and education generally. Dr. Louise Rabinovitch of New York read a paper on the Duty of States in Preventing the Propagation of Crime, which she said was mostly hereditary. Dr. Wellenbergh of the Hague made some recommendations with regard to penalties in the case of aged first offenders—that was to say, such as were above the age of 70 years. On Sept. 14th the Congress resumed its discussion of the physiological action of criminals. M. Treves of Turin, Professor Benedikt of Vienna, and M. Drill of St. Petersburg taking part. A motion proposed by M. Albanel of Paris was then adopted. It recommended that children breaking the law should be examined before being brought into court, and if found to be degenerate should be placed in special educational establishments. The Congress supported a proposition

introduced by Mr. Macdonald of New York with regard to a combination of a psychical and physical laboratory with the Ministry of Justice at Washington. Señor Falcon of Cuba delivered an address on Interesting Features in Criminals. In his closing speech M. Van Hamel, the president, thanked the delegates to the Congress and observed that England was represented for the first time. It was decided that the next meeting should take place in Turin in 1906.

**VACCINATION GRANT.**—Mr. Henry Harris, L.R.C.P., L.R.C.S. Edin., of Clevedon, Somerset, has been awarded for the second consecutive time the Government grant for successful vaccination.

**PRESENTATION TO A MEDICAL PRACTITIONER.**—Mr. C. F. Laing, M.B., M.S. Glasg., formerly deputy medical superintendent at the County Asylum, Parkside, near Macclesfield, has been the recipient of a presentation of silver plate with an illuminated address from the resident staff of the asylum as a mark of respect and esteem on the occasion of his appointment to the post of medical superintendent at the Somerset and Bath Asylum at Wells.

**ST. JOHN AMBULANCE BRIGADE FOR EXETER.**—A meeting was held at Exeter on Sept. 24th, under the presidency of the mayor, for the purpose of forming a St. John Ambulance Brigade for Exeter. Dr. Vernon, deputy-commissioner, gave an interesting account of the work of the order and mentioned that three attempts to form a division of the brigade in that city had failed. The meeting unanimously resolved to establish a brigade in Exeter and several members were enrolled.

**SOUTHEND HOSPITAL.**—On Sept. 28th the Mayor of Southend opened a new ward at the Victoria Hospital. This new addition to the hospital owes its inception to the generosity of the late Mr. G. F. Frooms, who gave £1200 for the building and £1000 as an endowment, in memory of his late wife. The hospital at Southend was opened in 1887 in honour of the Jubilee of Queen Victoria. On the occasion of the Diamond Jubilee the Nursing Institution and men's wards were added.

**A "CONSCIENTIOUS OBJECTION."**—At Bideford on Sept. 24th a gardener applied for a certificate of exemption from vaccination for his infant on the ground that a niece had suffered from the effects of the operation. Admiral Sir William Dowell told the man that he should read about the outbreak of small-pox in London and the late epidemic at Gloucester; he also said that although the gardener was mistaken he could not refuse to grant the certificate.

**REDRUTH BOARD OF GUARDIANS.**—At the meeting of the Redruth Board of Guardians held on Sept. 27th a communication was received from the Local Government Board informing the guardians that unless they proceeded at once to the division of the union into four districts and the appointment of four relieving officers the Board would have to issue an order directing this to be done. The guardians after discussing the matter decided to inform the Local Government Board that they declined to appoint four relieving officers, as they considered three to be sufficient.

## BOOKS, ETC., RECEIVED.

- BAILLIÈRE, TINDALL, AND COX**, 8, Henrietta-street, Strand, W.C.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

- ABRAHAM, J. JOHNSTON**, M.B., B.Ch., B.A.O. Dub., L.M. Rotunda, has been appointed House Surgeon to the West London Hospital.
- ALSOPT, T. O. F.**, M.B., M.S. Edin., M.R.C.S. Eng., has been appointed Public Vaccinator for the South-Eastern District, Victoria, and Officer of Health for the Shire of South Gippsland, Victoria.
- BAILEY, J. C. M.**, M.B. Lond., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician and House Surgeon to the West London Hospital.
- BROAD, W.**, M.B., has been appointed Medical Officer to the Hospital at Narrandera, New South Wales.
- DEANS, JOHN**, M.D., has been appointed Public Vaccinator for the South-Western District, Victoria.
- FETHERSTON, R. H. J.**, M.B. Edin., L.R.C.S. Irel., has been appointed Acting Officer of Health for the City of Prahran, Victoria, (temporary).
- FINDLAY, JOHN**, M.B., M.Ch. Aberd., has been appointed Second Assistant Medical Officer, Dorset County Asylum, vice George Potts, L.R.C.P. and S. Edin., resigned.
- HAY, J. B.**, M.B., M.S. Edin., has been appointed Officer of Health for the Shire of Echuca, Victoria.
- HOWSE, N. R.**, F.R.C.S. Eng., V.C., has been appointed Government Medical Officer and Vaccinator at Orange, New South Wales.
- HOYSTEAD, L. N.**, M.R.C.S., L.R.C.P., has been appointed Public Vaccinator for the South-Western District, Victoria.
- NOALL, WM. PAYNTER**, M.B. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Surgeon to the East London Hospital for Children, Shadwell, E.
- RICHMOND, MARSHALL LEIGH**, L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator to the Mary Tavy District of the Tavistock Union.
- THORNTON, R. G. C.**, M.B., B.A.O., R.U.I., has been appointed District Medical Officer of Wellington (Salop).
- WARNER, ALLAN**, M.D. Durh., M.R.C.S., L.R.C.P., Lond., has been appointed Resident Medical Officer of the Leicester Isolation Hospital.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

- BIRMINGHAM AND MIDLAND EYE HOSPITAL.**—Resident Surgical Officer. Salary £100 per annum, with board and attendance.
- BRIDGNORTH AND SOUTH SHROPSHIRE INFIRMARY.**—House Surgeon. Salary £100, with board and lodgings.
- BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL**, Church-street, Queen's-road, Brighton.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.
- BRISTOL GENERAL HOSPITAL.**—Assistant House Surgeon. Salary £70 per annum, with board, residence, &c.
- BURTON-ON-TRENT INFIRMARY.**—House Surgeon. Salary £120 for the first year and £140 for the second year, with board, furnished rooms, coal, and light.
- CHICHESTER INFIRMARY.**—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.** Victoria-park, E.—Second House Physician for six months. Salary at rate of £20 per annum, with board, washing, and residence.

**CLAYTON HOSPITAL AND WAKEFIELD GENERAL DISPENSARY.**—Senior House Surgeon, unmarried. Salary £120 per annum, with board, lodging, and washing.

**CORNWALL COUNTY ASYLUM,** Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, apartments, laundry, &c.

**COUNTY ASYLUM,** Mickleover, Derby.—Senior Assistant Medical Officer. Salary £130, rising to £150 per annum, with apartments, board, washing, and attendance. Also Junior Assistant Medical Officer. Salary £110, rising to £130 per annum, with apartments, board, washing, and attendance.

**DENBIGHSHIRE INFIRMARY,** Denbigh.—House Surgeon. Salary £100, with board, residence, and washing.

**ESSEX COUNTY ASYLUM,** Brentwood.—Junior Assistant Medical Officer. Salary £140 per annum.

**GLASGOW ROYAL ASYLUM FOR LUNATICS.**—Physician Superintendent. Salary £1000 per annum, with house, coal, gas, and water-supply.

**GRAVESEND HOSPITAL.**—House Surgeon. Salary £90 per annum, with board and residence.

**HAMPSTEAD HOSPITAL,** Parliament-hill, N.W.—Dental Surgeon.

**HOLLOWAY AND NORTH ISLINGTON DISPENSARY.**—Two Honorary Medical Officers.

**HOSPITAL FOR SICK CHILDREN,** Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, washing allowance £2 10s. with board and residence; also Surgeon Dentist.

**HOSPITAL FOR WOMEN,** Soho-square, W.—Assistant Physician.

**INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.**—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

**LIVERPOOL HOSPITAL FOR CANCER AND SKIN DISEASES.**—Honorary Medical Officer.

**MANCHESTER CHILDREN'S HOSPITAL,** Pendlebury.—Medical Officer. Salary £180 per annum.

**MIDLOTHIAN DISTRICT ASYLUM.**—Assistant Medical Officer, single. Salary £200, with furnished rooms, board, washing, and attendance.

**NORTH-EASTERN HOSPITAL FOR CHILDREN,** Hackney-road, N.E.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

**NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL,** Hartshill, Stoke-upon-Trent.—House Physician. Salary £100 per annum, increasing £10 per annum, with furnished apartments, board, and washing.

**NORTH WALES COUNTIES LUNATIC ASYLUM,** Denbigh.—Second Assistant Medical Officer. Salary £120 per annum, rising to £160, with board, residence, and washing.

**PADDINGTON GREEN CHILDREN'S HOSPITAL,** London, W.—House Physician, also House Surgeon, both for six months. Salary at rate of 50 guineas a year, with board and residence.

**ROYAL CORNWALL INFIRMARY.**—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board and apartments.

**ROYAL FREE HOSPITAL,** Gray's Inn-road, W.C.—House Physician (Male) and Casualty House Surgeon (Male), both for six months. No salary, but board, &c., provided. Also Resident House Physician (Female) and Resident House Surgeon (Female) both for six months. No salary, but board, &c., provided.

**ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST,** Ventnor.—Resident Medical Officer, unmarried. Salary £150, with board and lodging.

**ROYAL VICTORIA HOSPITAL,** Belfast.—Medical Superintendent. Salary £300 per annum, with board and apartments.

**ST. MARY'S HOSPITAL,** Paddington, W.—Casualty Physician. Salary £75 per annum.

**STAFFORDSHIRE GENERAL INFIRMARY,** Stafford.—Assistant House Surgeon. Salary £80 per annum, with board, lodging, and washing.

**STIRLING DISTRICT ASYLUM,** Larbert, N.B.—Junior Assistant Medical Officer. Salary £100, with board, &c.

**TEIGNMOUTH HOSPITAL,** S. Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

## Births, Marriages, and Deaths.

### BIRTHS.

**FALLA.**—On Sept. 29th, at Adelaide Lodge, St. Heliers, Jersey, the wife of Walter Falla, M.R.C.S., L.R.C.P., of a daughter.

**MADDEN.**—On September 19th, at Cairo, the wife of Frank Cole Madden, F.R.C.S., of a son.

**MUDIE.**—On Sept. 28th, at York Lodge, West Norwood, the wife of Arthur Mudie, L.R.C.P. Edn., L.R.C.S. Edin., L.F.P.S.G., of a daughter.

### MARRIAGES.

**GOODFELLOW—ROBERTSON.**—On the 25th September, at St. Wilfrid's Church, Northenden, Cheshire, by the Ven. Archdeacon Woosnam and the Rev. Canon Ford, Thomas Ashton Goodfellow, M.D. Lond., of Didsbury, to Eleanor Winifred, only daughter of W. J. Robertson of Northenden.

**SAMWAYS—SIM.**—On Thursday, September the 26th, at Kensington Chapel, Allen-street, W., by the Rev. C. Silvester Horne, M.A., Daniel West Samways, M.D., M.R.C.P., D.Sc., of Mentone, to Sarah Sophia, widow of the late Captain A. D. Sim, Argyll and Sutherland Highlanders, and youngest daughter of the late J. C. Bolton of Carbrook, Argyllshire.

*N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### "CREDULITY, SUPERSTITION, AND FANATICISM."

THE above words form the heading of one of Hogarth's most telling plates, and were he alive now his biting pencil would find an infinity of subjects in the various forms of fraud and credulity rampant among us. We take the following paragraphs from a contemporary, under date Oct. 1st:—

"Yesterday, at the different schools under the London School Board in the Marylebone Division, men were busily engaged in distributing to the scholars to take home to their parents the following circular:—

'London School Board's children and Vaccination.'

'Parents, do not allow your children to be inspected by the Public Vaccinators. There is no law to compel you. Keep the children away from school rather than run the risk of their being poisoned with filth taken from animals, which the doctors call vaccine, the evil effects of which they themselves do not understand. Parents, will you allow your children to be made ill and liable to take diseases in order to allow some doctors to have good positions and well-lined purses. Remember, a large number of the doctors themselves are against vaccination. Abolish the filthy practice altogether. When the circular announcing the examination reaches you, send in your notice of objection, so that the authorities may learn how strongly the people object to these measures for forcing vaccination upon them.'

This drivell needs no further comment.

The Viavi swindlers are also abroad in the land and are distributing their dirty little pamphlets throughout Wimbledon. Their plan of action is the same as that of other quacks. Their literature consists of nasty little books full of innuendoes and hints about sexual matters, salted with excerpts from the medical journals and papers by medical men, so artfully detached from their context as to make it appear to an ignorant person that the treatment of the quack is endorsed by the journal or medical man in question. Finally comes a paper of questions to be filled up, such questions dealing with every imaginable symptom and one or more of which nearly everyone has experienced at some time or another. "No application will be considered in which the full name and address is not given," a remark which is perhaps the gist of the document. From Australia comes the circular of another quack, one Dr. Critchett Gorrick, M.D., M.P.S., Spec. Cert. in Tox. & Spec. Cert. in A. Ch. This creature has established himself in the place lately occupied by Harman Tarrant and sends out almost, if not absolutely, identical circulars. First, of course, he asks his patient's full postal address and name, secondly comes a list of 85 questions many of which are concerned with symptoms relating to sexual matters. Amongst them, however, we notice such questions as "Dreams"? There is probably no one who does not have dreams. The one important question, however, is the following, No. 80: "Are you sending the £1 by P.O.O. or Registered Letter?" Another one is, "Describe the urine after standing in a warm place for 50 hours." The question does not make it clear whether the secretion or the secretor is to stand for this long time in a warm place, but if the urine is meant the purport is obvious. Of course, the urine would become turbid from decomposition and upon this natural event "Dr." Gorrick would build up a fearsome account of disease from which his dupe would be told he was suffering. The full name and address of course opens the door to blackmail, and although "Dr." Gorrick professes to destroy his dupes' papers when returned to him we doubt whether he does so. "Dr." Gorrick, we notice, reserves the right to return the £1. We wonder how many he returns. We still live in hopes of the day coming when quacks and patent medicine vendors shall be licensed, and by a licence we do not mean any form of diploma, but a tax, and that a heavy one. In Great Britain no one may sell beer or spirits or tobacco without a licence, and the said licence does not in any way guarantee the purity of either the drink or the tobacco. If a quack, whose calling is, we regret to say, perfectly legal, had to pay a licence he might find his game not worth the candle.

### A DIFFICULTY UNDER THE NOTIFICATION ACT.

AT Lancaster Castle on Sept. 28th a man was summoned on behalf of the Lunesdale Rural District Council, under the Public Health Act, for exposing himself while suffering from an infectious disease, and Dr. William Wingate-Saul of Lancaster was summoned for aiding and abetting the offence. The case for the prosecution was that on July 30th the patient was certified by Dr. Wingate-Saul in a notification to Dr. D. J. M. Bone, the medical officer of the Lunesdale Union, as suffering from scarlet fever. On August 1st he was moved from the house where he had been in service to a cottage near by. Dr. Bone having made some inquiries received from Dr. Wingate-Saul a telegram containing the words: "I accept all responsibility of moving case from Halton Park." Dr. Wingate-Saul

was therefore joined in the information. On August 14th the patient travelled by train from Caton to Leeds, en route for Charleton, near Nottingham, and there appear to have been no precautions taken about his removal. He was driven down to the station in an open vehicle, the railway authorities and the medical officer of health having no intimation that such a patient was to be moved. On hearing the facts from the clerk of the Lunesdale Rural District Council the Midland Railway Company caused the whole train to be disinfected. Dr. Bone, called in support of the prosecution, said that he considered that in a case of scarlet fever it took from five to eight weeks for the disease to run its course. He had known cases which had taken 10 weeks. Dr. Bone's cross-examination was as follows:—Do you consider, never having seen this man, that your opinion on August 14th is of more value than that of his medical attendant who had been attending him during the illness?—I never gave any opinion as to whether the man was infectious on August 14th or not. If he fell ill at the end of July I should say most decidedly that he was infectious. I received the certificate that he was suffering from the disease on July 30th.—There was nothing on that certificate to show how long the man had been suffering from scarlet fever?—There was not.—Therefore you cannot say how long this man had scarlet fever?—Yes, I inquired.—But that is not evidence. You cannot say from your own knowledge how long this man has been suffering from scarlet fever?—I cannot.—In your experience you have come across some very mild cases of scarlet fever?—Yes, of course I have.—Cases almost difficult to diagnose as scarlet fever?—Sometimes that is so.—And do you agree that a second attack is generally much milder than the first attack?—Not necessarily. I have seen so few secondary attacks that I could give no opinion on them.—Presuming that this was a second attack of scarlet fever would you say it would be likely not to be so severe as the first?—It is not necessary.—In further cross-examination witness said he would not deny that if the patient were in a state of desquamation when the medical man was called in that the desquamation would cease in a fortnight.—Dr. H. F. Oldham, medical officer of health of Morecambe, having given evidence, said in his cross-examination that he did not know that the man was in an infectious state at all when he travelled, neither did he know that he had scarlet fever.—Dr. Wingate-Saul submitted that there was no case to answer. The onus was on the prosecution to prove that the man was in an infectious condition. There had been nobody called who could say that this man was in an infectious condition. They had a few remarks from Dr. Bone on the subject of scarlet fever in general cases, but he said: I cannot tell you when this man fell ill with scarlet fever, and I cannot say that he was suffering from infectious disease at the time he was removed.—The Bench retired, and after a short absence the chairman (Mr. G. B. Dawson, LL.B.) said it was not proved that the patient was suffering from scarlet fever at the time he travelled and therefore both cases would be dismissed.—Dr. Wingate-Saul's application for costs was refused, the chairman remarking that it was the duty of a public authority to try to prevent the spread of disease.—It will be seen that the prosecution failed on the technical points: (1) that there was no evidence as to the date of commencement of the illness; and (2) that the medical witnesses for the prosecution had no personal knowledge of the case.

#### HIGH FREQUENCY CURRENTS AND DIABETES.

To the Editors of THE LANCET.

SIRS,—Can you or your readers give me any information or references concerning the value of the D'Arsonval high frequency currents in the treatment of diabetes mellitus?

I am, Sirs, yours faithfully,  
Sept. 12th, 1901. S. L. B. W.

#### "MEMBRANOUS COLITIS."

To the Editors of THE LANCET.

SIRS,—I would advise your correspondent "Worried" (THE LANCET, Sept. 21st, p. 826) to try injection into the bowel of one pint or more of infusion of quassia every day for a fortnight, dieting, and warmth.

I am, Sirs, yours faithfully,  
Sept. 29th, 1901. A.

P.S.—I have tried the above and have been successful.

#### POCKET-HANDKERCHIEFS FOR THE TUBERCULOUS.

To the Editors of THE LANCET.

SIRS,—I am advised by the medical officer of health to send you for publication through your columns the appended methods of treating Japanese serviettes so as to render them impervious and thus suitable for isolating the sputa of consumptive persons for a reasonable length of time. The process appears to slightly toughen the texture and leaves it pliable and without the crispness which is the objectionable feature in more durable impervious papers. Cotton and other fabrics may be treated in the same manner.—I am, Sirs, yours faithfully,

G. H. LOCK,

Chief Clerk in the Tuberculosis Department,  
Public Health Office, Manchester.

[INCLOSURE.]

A method by which Japanese serviettes may be rendered impermeable

to serve as pocket-handkerchiefs for consumptive persons, by G. H. LOCK, chief clerk in the Tuberculosis Department, Public Health Office, Manchester.—Dissolve with gentle heat two ounces of *cera alba japonica* and one ounce of paraffin (or spermaceti) wax in about 10 ounces of turpentine. Spread a thickness of about a dozen serviettes on a non-absorbent surface and brush over with the warm solution until well saturated. Separate and hang to dry for several days. A better, but more expensive, solution is prepared as above, with the addition of a small quantity of pure rubber thoroughly dissolved in turps. The quantities of the ingredients may be varied with advantage with regard to the special texture of the serviettes to be treated. The more open the texture the larger will be the amount of Japanese wax required.

**Income-tax.**—THE LANCET of July 4th, 1896, deals with our correspondent's question. If his place of residence is used partly for professional purposes a sum not exceeding two-thirds of the annual value or rent should be deducted when making the return to the Income-tax Commissioners. A model form of return is given in the issue of THE LANCET referred to.

**Uncertain.**—Our correspondent must send us more details of the appointment which he wishes to hold. The necessary qualifications depend in some measure upon the population of the district to which he may be appointed.

**A. M.**—We fear our correspondent can make no legal claim for extra remuneration.

**H. J.**—Yes.

**ERRATUM.**—In THE LANCET of Sept. 28th, p. 845, col. i., line 16, the words "left cerebral vein" should be *left middle cerebral vein*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

#### METEOROLOGICAL READINGS.

**SATURDAY (12th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

#### SOCIETIES.

**TUESDAY (8th).**—SOCIETY FOR THE STUDY OF INEBRIETY (11, Chandos-street, Cavendish-square, W.).—4 P.M. Papers:—Mr. C. Smith (Maidstone): Are Southern Nations Sober as compared with Northern Nations? if so, why? Some omitted factors in the theory of Dr. Archdall Reid.—Dr. M. Westcott: A Note on Sea Voyages in the Treatment of Inebriety.—Dr. W. Westcott (President): A Review of Recent Progress in the Treatment of Inebriates in Reformatories under Public Bodies by authority of the Act of 1898. The Council will meet at the same place at 3.30 P.M.

**WEDNESDAY (9th).**—HUNTERIAN SOCIETY (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Dr. Mitchell Bruce: Chest Complications in Abdominal Disease. (Hunterian Lecture).

**DERMATOLOGICAL SOCIETY OF LONDON** (11, Chandos-street, Cavendish-square, W.).—5.15 P.M. Demonstration of Cases of Interest.

**THURSDAY (10th).**—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Specimens will be shown by Dr. H. Macnaughton Jones. Dr. Travers: Intestinal Obstruction caused by Unsuspected Uterine Fibromyoma simulating Appendicitis.

**FRIDAY (11th).**—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. J. J. Clarke: Note on a Painful Condition of the Twelfth Pair of Ribs.—Mr. T. Bryant: A Case of Displaced Strangulated Femoral Hernia.—Mr. C. Wallace: Wounds of Joints and their Treatment.—Mr. C. Mansell Moullin: Omental Fixation for Ascites.

#### LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (7th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. J. F. Payne: Clinique. (Skin.)

**TUESDAY (8th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. C. T. Williams: Clinique. (Medical.)

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Queen-square, Bloomsbury).—3.30 P.M. Dr. Beevor: Cerebral Localisation.

**WEDNESDAY (9th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. P. J. Freyer: Clinique. (Surgical.)

**THURSDAY (10th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

**THE HOSPITAL FOR SICK CHILDREN** (Gt. Ormond-street, W.C.).—4 P.M. Dr. Lees: The Heart of the Child.

**FRIDAY (11th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. D. Grant: Clinique. (Ear.)

#### EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

#### MANAGER'S NOTICES.

##### THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1901, which was completed with the issue of June 29th, and the Title-page to the Volume, were given in THE LANCET of July 6th.

##### VOLUMES AND CASES.

VOLUMES for the first half of the year 1901 are on sale. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also on sale. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

##### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year ... ..	£1 12 6	One Year ... ..	£1 14 8
Six Months ... ..	0 16 3	Six Months ... ..	0 17 4
Three Months ... ..	0 8 2	Three Months ... ..	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER. THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—Surrey Advertiser, Reading Mercury, Leeds Mercury, Bristol Mercury, Glasgow Herald, Mining Journal, Hertfordshire Mercury, Daily Mail, Local Government Chronicle, Yorkshire Post, Sanitary Record, Public Health, Engineer, Daily Telegraph, Bath Chronicle, British Sanitarian, South African Weekly News, Liverpool Daily Post, The Guardian, Windsor and Eton Express, The Ardrossan and Salicoats Herald, Echo, Manchester Courier, Birmingham Post, Dundee Advertiser, Kent Argus, Grimsby Gazette, Kentish Observer, City Press, Halifax Courier, Western News, Hong-Kong Telegraph, Bury Free Press, Doncaster Chronicle, &c.

### Communications, Letters, &c., have been received from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

## An Introductory Address

*Delivered at the Opening of the Winter Session at the  
Yorkshire College, Leeds, on Oct. 2nd, 1901.*

BY SIR WILLIAM S. CHURCH, BART.,  
M.D. OXON., F.R.C.P. LOND.,  
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

GENTLEMEN,—I must, in the first place, thank the governing body of the Yorkshire College for having invited me to come among you, for I feel how great is the compliment to have been asked to address you, especially when I remember the distinguished men who are or have been connected with your college and teaching staff and are much better fitted than myself for the task.

In the great educational progress that the nation made during the latter half of the last century it is noticeable that the promotion of general education was more successfully carried out by many of the great provincial cities than in the metropolis. In the case of medical schools the provincial ones naturally could not attain the same reputation as those in London, partly on account of the small numbers attending them and partly from the want of means and facilities for the requisite studies. Time has, however, in this as in many other matters brought about remarkable changes, and the medical schools of London look now with envious eyes at the liberality with which all branches of learning are supported in the great provincial centres of commerce. Science and with it medicine has appealed, and not in vain, to the people of the great northern counties of Yorkshire and Lancashire and nowhere is greater munificence manifested in their support.

The Yorkshire College, originally the Yorkshire College of Science, has for nearly 30 years held a distinguished position among the educational bodies of the kingdom and especially is this the case with the medical school which forms one of its component parts. The Leeds School of Medicine, established 70 years ago, rapidly acquired a high reputation, and when the Yorkshire College was in 1887 admitted to the Victoria University its medical department acquired, as it was fully entitled to, a recognised university standing.

In the history of Leeds, and notably in connexion with its medical school, reference must be made to the remarkable family of the Heys. The first William Hey was active in promoting the foundation of your infirmary in 1767, and for some 30 years was attached to it as surgeon. A friend of the illustrious Priestley, he took the liveliest interest in all scientific and literary progress, and was the first President of the Leeds Literary and Philosophic Society. At the commencement of the last century he gave, as opportunities arose, courses of anatomical instruction in the infirmary on the bodies of executed criminals and his name will ever be honoured as one who greatly improved the art of surgery. His son William succeeded him as surgeon to the infirmary and his grandson William was one of the founders of your medical school; with him were associated Dr. Williamson, remarkable not only for his professional knowledge, but also for his active public life; Dr. Thorp; and Mr. Pridgin Teale, whose son worthily carries on his father's work and who as one of your consulting surgeons it is still your good fortune to have among you.

How wonderful have been the changes since the time when William Hey published his "Practical Observations in Surgery" illustrated with cases (1803). Leeds I find described at that time as a populous market town containing in the year 1801 11,599 houses and 53,162 inhabitants, and it is noted as having flagged footways on both sides of the streets. By the kindness of the town clerk, Mr. Jeeves, I learn that now Leeds contains 94,770 houses and 428,953 inhabitants, more than eight times the number of houses and people it did 100 years ago. Returning to the old description of Leeds, mention is made of its spacious infirmary which, founded some years earlier, was rebuilt by the liberality of the inhabitants of the town in 1786; of three sets of almshouses and a charity school. Leeds was fortunate also in the possession of a free grammar school, an old foundation, due to the pious action of William Sheffield in 1552 and greatly benefited in the following century by John Harrison (1664)

No. 4076.

and Godfrey Lawson, the Mayor (1692). Possessing this advantage we find that Leeds long ago had its contributors to science and art, for among those educated in the grammar school during the eighteenth century we find Dr. John Berkenhout, a man of surprising industry and an encyclopædic writer, and Benjamin Wilson, the portrait painter, the friend of Hogarth and Zoffany, who was not only a considerable artist, but a man of science as well, obtaining the gold medal of the Royal Society for his researches in chemistry and electricity, and especially for his services in devising improvements in the construction of lightning conductors.

It is difficult for the present generation to bear in mind the enormous changes which have taken place during the last 100 years. Steam and electricity have nearly realised the wonders of Aladdin's lamp, and Leeds has participated to the full in the material and educational progress which the kingdom has enjoyed. Medicine has had its share in this general advance, and greater progress has taken place in all branches of medical knowledge during the last than in all the centuries which preceded it; not only have great improvements been witnessed in the practice of medicine and surgery and in the knowledge of the action of drugs on the system, but the State, recognising the importance of national health, has taken part in developing a new department of medicine—namely, that of preventive medicine and sanitary science.

While fully acknowledging the debt we owe to the founders of medicine it is clear that however excellent the practice of Hippocrates, Galen, Celsus, and their followers may have been it was entirely due to empirical knowledge, the result of the observation and study of clinical symptoms. On them they, and to a still greater extent their followers, founded theories of disease which, like all other theories, were "fond imaginations vainly conceived," and led to advance neither in knowledge nor practice. The art of healing made no progress whatever during the decline of the Roman Empire, and later the Arabians were but plagiarists of the Greeks and, with the exception of Rhazis, added nothing to our medical knowledge. To them belongs the credit of keeping alive the flickering light of medicine during what are spoken of as the dark ages, when knowledge and learning in Western Europe were at a very low ebb, and but for them the writings of the Greeks would have been wholly forgotten. With the revival of learning and the re-introduction of the knowledge of Greek an undue reverence for the masters of antiquity became prevalent. The writings of Galen were supposed to be infallible, and those who ventured to dissent from their absolute truth were regarded by the learned doctors of Paris and London in much the same light as the ecclesiastical courts looked upon heretics. So strong was this feeling that in 1559 my own college refused the fellowship to Dr. Geynes because he ventured to doubt the infallibility of Galen, and about the same time it declined to admit Dr. Hook to the examination for its licenseship because he had the honesty to say that he had not read Galen's works.

With the Renaissance the study of anatomy became general in Italy. Sylvius, Fallopius, Vesalius, and others placed anatomy on a firm basis, and by showing the errors in the anatomical knowledge of the ancients enabled their followers and successors to break through the prison-like bonds in which medical knowledge had been confined. At a somewhat later period Harvey's discovery of the circulation and his methods of experimentation gave an impulse to the study of the functions of organs in the living, out of which physiology, as we now understand the term, arose. We are apt to forget how slow was the acquisition of physiological knowledge, even after Harvey's time; it was not until upwards of 100 years later, when Black had demonstrated the presence of carbonic acid in expired air and Priestley had succeeded in isolating oxygen, that it was possible for real advances to be made in physiology, and consequently little or no progress was made in the practice of medicine from the time of Sydenham until the practice of auscultation was introduced. I do not mean to imply by this that no improvements took place in practice; great advances were made in surgery and some in medical treatment, but our knowledge of the nature and causes of disease did not advance. Jenner, it is true, more than 100 years ago, by keen observation and patient experimentation, made his great discovery, and not only robbed small-pox of half its terrors, but placed in our hands a clue to the nature of infectious diseases which indirectly,

perhaps, but none the less surely, led to the later discoveries which we owe to the genius of Pasteur and Lister.

The late Sir William Roberts in his interesting Harveian Oration (delivered in 1897) remarks that a sharp distinction must be drawn between the science of antiquity and the science of to-day. Their greatest intellects were concerned in metaphysics and literature rather than in systematising and inquiring by way of experiment into the secrets of nature. The ancients, and more especially the Greeks, possessed a large mass of information concerning nature and natural objects, but from want of general principles and coördination failed to systematise the knowledge they possessed.

It is not my intention to attempt to trace the development of our scientific knowledge during the past century or the influence it has had on medicine. The concluding years have been marked by the discovery of a new province of nature and by the rise of a new science—bacteriology, or the study of the nature of micro-organisms and the part they play either for our advantage or disadvantage in the universe. At present we are only on the threshold of their kingdom and the part they play in nature is as yet but imperfectly known. The problems of the causes of our susceptibility or immunity to their attacks have yet to be explained and present vast fields for research and experimentation; as yet we know that certain forms are invariably associated with certain morbid conditions, and we can go a step further and state with confidence that they are the essential causes of those conditions and that without their presence in our bodies we should not manifest the deviations from the normal state which we call disease. The discovery of their presence and the dependence of disordered health on their activity have already necessitated so great a change in our views of disease that it may with truth be said that a new era has already commenced in medicine.

Many whom I now have the honour to address are about to enter my own profession. I shall therefore devote myself to a brief consideration, not of the amount and kind of knowledge that is required for the study and practice of medicine, but rather of the spirit and frame of mind in which you should approach your future work, the methods by which it should be carried out, and the effect which, in my opinion, your work should and will have on your minds and lives.

Medicine embraces so extensive a range of knowledge that, in the words of Dr. Thomas Young, "there is no science which requires so penetrating an intellect, so much talent and genius, so much force of mind, so much acuteness of memory as medicine. For the full attainment of its proper and ultimate object it requires also the possession of stability of judgment, rapidity of decision and immovable firmness and presence of mind, readiness of recollection, coolness, flexibility of temper, elegance of manners, and a profound knowledge of mankind and the secret recesses of the human heart." Dr. Young has enumerated a most formidable array of requirements for those who look forward to practising the art of healing; it is too much to expect that all these qualities can be united in any of us; it is only a gifted few who can hope to command a portion of such varied qualities. Dr. Young himself does not seem sanguine that many can be found who would meet his requirements and come up to his standard, for he goes on to say: "Our only hope for attaining these qualities is by means of a good education united with opportunities of becoming acquainted with the world and habits of intercourse with society."

You have all received a good general education and are now entering on your special and professional studies; the better and more advanced your general education has been with the greater ease will you become initiated in your new lines of work. It was a great step forwards in the right direction when the various licensing bodies decided that no man should be admitted as a student of medicine without giving evidence of possessing a more or less satisfactory elementary education. I wish that a higher standard of general knowledge could be insisted on and that the entrance to our profession was instituted on a broader basis. The principles of the sciences of physics, chemistry, and biology should be acquired before the five years of professional study are commenced, for they are none too long for affording time in which you may obtain some practical acquaintance with the many special branches into which the progress of our knowledge has necessitated the breaking up of medicine and surgery.

Great difference of opinion exists among those well qualified to judge as to the value of different kinds of

knowledge in training and developing the mind. I will not attempt to enter into the question; it is the way in which a subject is taught rather than the subject matter itself which appears to me to be most important. Without impugning the value of science, if properly taught, to boys as a training for the mind I am quite satisfied that a fair acquaintance with the old classical languages Greek and Latin very greatly facilitates your progress in science. The terminology, not only of medicine, but of the sciences with which you have to become familiar—physics, chemistry, biology, anatomy, physiology, pathology—is for the most part derived from Greek or Latin, and if you have not a fair acquaintance with them the terminology you meet with is not only difficult to master but is actually repugnant to many.

Nor should we forget that the professional character is not the only one which those engaged in a profession have to support. You will not always be the doctor; as a companion, friend, and citizen you have other duties to perform and other opportunities of showing that you have not neglected your talents. Our profession has always claimed to be a liberal and learned one; in no way can its status be maintained and raised, if its members cannot hold their own in general society as men of intelligence and culture. Moreover, nothing more increases our capacity for pleasure in our moments of leisure than having an interest and some knowledge of a special subject, be it what it may. Dr. Johnson<sup>1</sup> remarks: "He that enlarges his curiosity after the works of nature demonstrably multiplies his inlets to happiness"; and I believe that no subjects are more calculated to increase our reverence and to elevate our minds than the contemplation of the works of nature and intelligent inquiry into the nature and causes of natural objects. In the words of the Roman poet,

"Jupiter est quodcumque vides, quodcumque moveris."—*Lucan*.

It is often said that we are such as education makes us. This is only partly true, for every man is essentially different from every other, so that no training can ever make two men alike in power or thought. Education and the acquirement of knowledge are not synonymous. Ruskin has remarked that "the great leading error of modern times is mistaking erudition for education."<sup>2</sup> In our profession not only the acquirement of knowledge but education is lifelong; we remain students so long as we remain at work, and our self-education terminates only with the cessation of active life, for it is one of the great advantages of your future work that it opens out an infinite field for speculation and thought and ever affords fresh material for research and experiment. In studying the natural sciences there is no danger of falling into the habits of the schoolmen—"who having subtle and strong capacities, abundance of leisure, and but small variety of reading, their minds being shut up in a few authors, as their bodies were in the cells of their monasteries, and thus kept ignorant both of the history of nature and times, they with infinite agitation of wit spun out of a small quantity of matter those laborious webs of learning which are extant in their books"—studying words and not matter which Bacon<sup>3</sup> says is the first distemper of learning. Very different will be your object; you will strive to work out and interpret the action of nature in health and disease; your search will be for facts and for the proof of these facts by way of experiment. "Knowledge is like current coin. A man may have some right to be proud of possessing it if he has worked for the gold of it and stamped it, so that it may be received of all men as true; and be assured that there is no part of the furniture of man's mind which he has a right to exult in but which he has hewn and fashioned for himself."<sup>4</sup> It is not on the mere acquisition of knowledge that we should pride ourselves; the possession of riches which have come to us from others may be very desirable, but they reflect no honour on the holder of them. Any real addition to the accumulated store of knowledge is a benefit to mankind and, however small, possesses more merit than in filling your minds from the general heap. Remember the words of the poet—

"Nec sibi, sed toti genitum se credere mundo."—*Lucan*.

"The real and legitimate goal of the sciences is the endowment of human life with new inventions and riches." Consider for a moment what science has done since Bacon wrote these words, and how marvellously the truth of them has

<sup>1</sup> Rambler, No. 5.

<sup>2</sup> Stones of Venice, Appendix vii.

<sup>3</sup> Novum Organum.

<sup>4</sup> Ruskin: Stones of Venice.

been exemplified in the 281 years which have elapsed since he submitted the "Novum Organon" to King James the First, together with a private letter in which he thus explains the object of his undertaking. "The work in what colours soever it may be set forth is no more but a new logic, teaching to invent and judge by induction, as finding syllogism incompetent for sciences of nature and thereby to make philosophy and sciences both more true and more active." What would be the condition of the world now had the discoveries of science not advanced with greater rapidity than they did in the centuries which preceded Bacon? How much of the advance has been due to his writings and the influence they have had on the world I will not attempt to discuss. Bacon himself was a product of his times and the revolt from the barren sophistry of the schoolmen and the ancient philosophers had set in before he was born, but no one can deny that his writings played an important part in directing the attention of the men of his own time and that immediately following to the fruitful fields of experimental philosophy. Five-and-twenty years after the appearance of the "Novum Organon" several ingenious men interested in the progress of mathematics and natural philosophy agreed to meet once a week to discourse upon subjects connected with those sciences. Four years later some of them having removed from London to Oxford held similar meetings there; the two societies joined and thus was instituted the Royal Society. It redounds to the credit of our profession that so many of the original members were physicians; among the Londoners we find the names of Goddard, Ent, Glisson, and Merrett; among the Oxford members Bathurst, Petty, and Willis. From the first the Royal Society declared the physical sciences and those which are promoted by experiment to be the objects of their attention, and experiment was the method they professed to practise in establishing the truth of their investigations.

The term "science" has been denied by some as applicable to medicine; they contend that it is an art and not a science. Definitions are always difficult and I will not attempt the task. The terms "art" and "science" have, however, been defined as dealing the one exclusively with things as they are in themselves and the other exclusively with things as they affect men. Science studies the relation of things to each other, art only their relation to men. If this definition embraces the truth medicine can claim to be both, for unless we know the real nature of the things we deal with and the relationship in which they stand to each other we cannot hope to apply them rightly. Whatever may be said of medicine in the past, we may now claim that it deals largely with facts and that our art is the application of our knowledge regarding them to the circumstances affecting human life both in health and disease. Your education should be, and will be here, carried out on scientific principles and you will find that the difficulty of arriving at facts in physiology and pathology constitutes the principal difficulty and is the main obstacle to the advance of curative medicine. These branches of knowledge deal with matters which are so much concealed from view, so involved and so disguised and obscured by a number of delicate and variable causes, that it requires the greatest care and judgment to separate the essential from the accidental—the proved from the probable. Modern means and methods of research give us great advantages over our forefathers in these difficult investigations, and the practising doctor is very greatly indebted to those who have devoted their energies and lives to scientific research in these most interesting but most ill-recompensed studies.

It is impossible in these days that any person, however gifted, can be conversant with all the methods of modern research, but he who has gone through some scientific training is placed in a much more favourable position for appreciating the value of the work and reputed discoveries of others than the man who has never received any such training and has spent his time in the acquisition of, I will not say knowledge, but information on certain subjects sufficient to enable him to scramble through his examinations, and has never learnt the difference between a fact scientifically proved and a statement made on insufficient data.

Credulity is not confined to the ignorant—far from it; it is remarkable how many persons of high intelligence and culture are ready, if they have not received some scientific training, to accept unproved statements and believe in them without questioning either their probability or the authority

of those who make them. This tendency to unquestioning belief is especially seen in matters pertaining to medicine, for the belief in the heaven-born doctor still lingers even among the educated. The wonders of science are so striking and to them so incomprehensible that they fail to see the differences between the probable and the improbable, the possible and the impossible. In no other way can we account for the popularity of numberless absurdities which have in their day enjoyed public favour and for the countless nostrums which swell the advertisement sheets of our present newspapers. Bishop Berkeley believed in the efficacy of tar-water as a universal panacea. He says: "It is good, not only in fevers, diseases of the lungs, cancers, scrofulas, throat diseases, apoplexies, chronic disorders of all kinds, but also as a general drink for infants. It strengthens their bodies and sharpens their intellects." None of his theological or philosophical writings commanded such numbers of readers as his "Siris," a work published in 1744, and entitled, "A Chain of Philosophical Reflections concerning Tar-water and divers other Subjects connected together and arising from one another." It is not the laity alone who are thus deluded; among many instances I could narrate of members of the profession being thus led astray I will only mention Dr. Hartley, a learned and philosophical physician, who was so convinced of the efficacy of Mrs. Stephen's powder for the cure of gravel and the stone that he succeeded in persuading the Government in 1739 to make up the sum of £5000 which she demanded for the prescription, £1387 only having been raised by private subscription. This valuable remedy is stated to have been composed of egg-shells and snail-shells with the snails in them calcined; ash-keys, hips and haws, swine-cress, and other herbs calcined; and chamomile and other herbs not calcined. By the irony of fate Dr. Hartley himself died from the disease in spite of having taken, it is said, 200 lbs. of the powder. The cures wrought nowadays by faith healing, Christian science, and other delusions are just as real to the uninitiated as is the removal of a tumour or the cure of an ague; their complete ignorance renders them incapable of forming a judgment as to the reality and nature of the conditions confidently asserted to have been cured. Do we not ourselves conduce to this ignorance on the part of the laity when we speak of curing disease? With few exceptions we do not cure the disease any more than we cure a broken leg; we place the leg or the patient into the best circumstances for nature to restore the health of our ailing patient or the bone of the broken leg.

It would far exceed the limits of my ability as well as of my time if I were to attempt to recount the enormous increase in our scientific knowledge which the last century witnessed. Let me remind you in passing of some of the advances which bear more particularly on the practice of medicine. I may instance the knowledge we now possess of the existence of motor centres in the brain. Although the clinical fact had been recognised for centuries that injuries to the brain were followed by loss of power in the limbs, and in some cases by loss of speech, it was not until experimental investigation was scientifically and continuously carried out that we arrived at the knowledge we now possess and became enabled in a limited number of cases to relieve the sufferers by surgical means and in some instances avert death. Here we see an example of the ease with which the relationship between facts may escape observation if not scientifically looked for and experimentally tested, for even the fact that the paralysis of the muscles occurring in hemiplegia was on the opposite side of the body to that on which the brain lesion was situated, although known to Aretæus and rightly explained by him as due to the decussation of the nerves in the spinal cord, had been forgotten and was not generally recognised until comparatively recent times. Again, in palmistry, which was at one time seriously studied by men of intelligence, whilst all sorts of fancies and superstitions were attached to the lines and folds in the hands and wrists and to the shape and form of the fingers, no one, so far as I know, associated clubbing of the finger ends with interference in the circulation nor transverse furrows on the nails with arrest of growth and nutrition.

How great a change has taken place in our views of the functions of organs since we have ascertained that the main organs of secretion, in addition to the functions we have long associated with them, elaborated other secretions which are probably not less necessary for the well-being of the individual than are those with which we had for years been acquainted. Our knowledge of micro-organisms and

the part they play in nature is but of yesterday, but what an amount of light has already been shed on what formerly appeared insoluble in connexion with infectious disease. How vast and interesting a field is thrown open to us by the little we yet know of serum-therapy and the action of the antitoxins in conferring immunity! Is it too much to hope that possessing, as we now believe, a key to much that has hitherto baffled us, we may in the near future make such progress in arresting or destroying disease that the advance during the nineteenth century may seem to those that follow us almost as slow and halting as we consider that which took place during the seventeenth and eighteenth centuries? May we not look with some confidence to the present century seeing cholera, plague, and malaria and other forms of fever, if not abolished, rendered comparatively innocuous? I am tempted to apply to our present position the words of Lucan, beautifully paraphrased by the late Dean Stanley—

"Never in earlier days our hearts to cheer  
Have such bright gifts of Heaven been brought so near.  
Nor ever has been kept the aspiring soul  
By space so short from so great a goal."

How is this goal to be attained? By patient and honest work, seeking the truth and not being contented until the truth can be plainly and palpably demonstrated. It is not given to everyone to make great discoveries, but we may all help in the work and bring, if we observe facts correctly, a fragment of stone or a grain of sand to assist in building the temple of knowledge.

I have now endeavoured briefly and very imperfectly to bring before you the manner in which you should approach the study of medicine. The time has passed when experience was the sole guide and clinical symptoms the sole means we possessed for recognising disease and judging of the state of our patients. Do not misunderstand me and conclude that experience and observation are not needed now; no amount of chemical or physiological knowledge will enable you to recognise disease or to treat satisfactorily those under your care. Observation and experience are as valuable and necessary as ever, but much more is required, for unless you approach your clinical work with minds already trained in scientific methods you will fail to appreciate and interpret aright the difficulties you will then encounter. You will find hereafter that the cases which cause you the greatest anxiety are those in which you are uncertain of the conditions with which you have to deal and where you cannot foresee the probable outcome of the symptoms before you. Recent progress enables us to stand on much firmer ground than we did but a few years ago. Bacteriology enables us to distinguish between certain forms of fever; and advances in pathological histology render it possible to discriminate innocent from malignant growths; by the aid of the Roentgen rays foreign bodies can be seen and located within us, whilst more exact information can be obtained in the diseases and injuries of joints and the condition of fractures; and we may hope that before long the wonderful x rays may reveal with greater certainty than at present changes in the tissues of our organs. There is no need for me to multiply instances; in a variety of ways we reap advantages from the progress of the other sciences and hopefully adopt them as a means for improving our art.

Let me, in conclusion, turn to the effect which the study of medicine has on those who pursue it. You must have already gathered from the tenor of my remarks that science appears to me to be the most ennobling of all pursuits; and as I claim medicine as a science it follows that it shares, and I believe more highly than any of the other branches, in this advantage. The old reproach, "Tres medici duo athei," is not, and never was, true, and I believe that among no class is true reverence for the Creator more strongly felt than by the followers of medicine. Unorthodox they have been and perhaps are. The anathemas of the Church which of old were so often directed against science arose from the hatred which the Church had to the spirit of inquiry, which is one and perhaps the most potent cause which leads men to enter our profession. The errors in the accepted beliefs of the Church soon became apparent to the students of the natural sciences and led them to regard with suspicion the truth of the dogmas and validity of the creeds promulgated by conferences of theologians who, however learned, were but fallible men. Without scepticism there can be no progress, but the charge that scientists were godless arose from the intolerance and bigotry of ecclesiastics.

"There lies more faith in honest doubt,  
Believe me, than in half the creeds."

It is needless in this assembly to refute the calumny that our education blunts our feelings and renders us callous to the sufferings of men and animals. The experience of the whole world disproves it; this charge was never made until recently and springs, in my opinion, from the same spirit of antagonism to inquiry and scientific knowledge which dominated the minds of the Papal inquisitors. The sentimentalist, ignorant alike of the methods and purposes of experimental investigation, allows his feelings to be played upon and his judgment perverted by the misrepresentations of a few who, I cannot help thinking, have other and more material reasons than either the sufferings of animals or the alleged evil effects of experimentation on those who practise it for the agitation they so noisily strive to maintain against physiological and pathological research. Our training produces an opposite effect; the desire to be useful to our fellow-creatures is next to the spirit of inquiry, if, indeed, it be second to that—the motive which leads many to our ranks. By general consent wherever sickness and suffering are found and however little may be the pecuniary reward we are found ready to succour to the best of our ability those in need of our aid. The battle-fields of our armies and the cholera and plague-stricken districts of our empire alike bear witness that we are not forgetful of Plato's definition of the duty of man: "Wherever his post is, whether selected by himself or assigned to him by his commander, there it is his duty to stand fast in the hour of danger, recking nothing of death or anything else except dishonour."

Before I conclude let me add a few words of encouragement to those who are to-day entering on a new life. You are commencing a period of keen competition, first among your fellow-students and subsequently in the world. Remember that you cannot all be prizemen; all are not equally endowed by nature, but all can make use of their gifts to the best purpose. I would remind you of the words of Marcus Aurelius, the last of the Stoics: "You have no special keenness of wit; so be it; yet there are many other qualities of which you cannot say you have no gifts that way. Do but practise them, they are wholly in your power; be sincere, dignified, industrious, serious, not too critical nor exacting, but considerate and frank. See how many good qualities you might exhibit for which you cannot plead natural incapacity or unfitness and how you fail to rise to your opportunities." Your opportunities here will be great, and I may venture to assure you that if you make use of them you will not fail, you will have fitted yourselves for the duties of life, and will not in the future have to repine over wasted years. Your success depends upon yourselves, upon your skill, character, and conduct; so employ your time now that at the close of your career you may be able to say, as did Percival Pott, one of the great surgeons of my hospital, "My lamp is nearly extinguished, I hope that it has burnt for the good of others."

## An Introductory Address

OR,

## OCCULTISM AND QUACKERY.

*Delivered at the Opening of the Winter Session at St. Mary's Hospital on Oct. 1st, 1901,*

BY WILLIAM HILL, B.Sc., M.D. LOND.,  
SURGEON FOR DISEASES OF THE EAR TO THE HOSPITAL.

GENTLEMEN,—We are confronted to-day with the spectacle of a number of students entering on an expensive course of study extending over at least five years in the hope of eventually joining, and making a competence in, the ranks of a profession which is already overcrowded. The total number of entrants to-day at the various medical schools in the kingdom we may put down at nearly 2000, and one may well pause to inquire whether these women and young men are wise, and whether it is really worth while going to the trouble and expense of a medical education at all. Why not start off and practise on the credulity of the public without let or hindrance by law? We live in an age when there is not only a large survival from the dark ages of superstition and a belief in occultism and in quackery of all kinds in medicine, but

there is positively a revival of the most remarkable character of an emotional form of occultism, a jumble of pseudo-science and irreligion. I allude to the various forms of faith-healing of which Christian Science is a type. There is, of course, money in the movement. In America "Divine healing" exhibits its success in one notable instance in the establishment of a school and college, a bank, a land and investment association, a printing and publishing office, and sundry "Divine healing" homes, and this prosperity is now to be extended by the foundation of a city or colony of converts who shall be united by the common bond of faith in Divine healing as transmitted in the personal power of their leader. The official organ of this movement announces that the personification of their faith "makes her religion a business and conducts herself upon sound business principles," and their leader publicly boasts of his vast financial returns. With emphatic protest on the part of each that he alone holds the key to salvation, and that his system is quite original and unlike any other, comes the procession of "metaphysical healer and mind-curist," "viticulturist and magnetic healer," "astrological health guide and phrenopathist," "medical clairvoyant," "esoteric vibrationist," "psychic scientist," and "mesmeric occultist." Some use or abuse the manipulation of hypnotism; others claim the power to concentrate the magnetism of the air and to excite the vital fluids by arousing the proper mental vibrations, or by some equally lucid and demonstrable procedure; some advertise magnetic cups, and positive and negative powders, and "absent treatment" by outputs of "psychic force," and countless other imposing devices. But what is especially interesting, they offer diplomas and degrees after a three weeks' course of study or merely after the reading of a book. You remember that Carlyle in alluding to the number of millions inhabiting the globe remarked without any special provocation that they were "mostly fools." I think to-day he would have added a condemnatory adjective.

"A series of superstitions and extravagant systems are conspicuous in the antecedents and bypaths of the history of medicine and are related to it much as astrology is to astronomy, or alchemy to chemistry; and, because medicine in part remains, and to previous generations was conspicuously an empirical art rather than a science, it offers great opportunity for practical error and misapplied partial knowledge. The legitimate recognition of the importance of mental conditions in health and disease is one of the results of the union of modern psychology and modern medicine. An exaggerated and extravagant, as well as pretentious and illogical, over-statement and mis-statement of this principle may properly be considered as *occult*."<sup>1</sup>

As I am addressing a mixed audience, many of whom have had no medical training, it may serve some useful purpose if I review simply and briefly the evolution and growth of medicine in early days, with special reference to the occult factor in ancient and modern times.

On examining the literature of ancient Egypt, Assyria, Greece, and Rome, even by the aid of English translations, one soon realises the obscurity in which the practice of medicine was enshrouded before the time of Hippocrates—that is, about 400 B.C.; but in dealing with the medical art as taught and practised by him we are dealing with extensive, systematic, and authentic records—records recorded mostly by himself. Medicine anterior to the "father of medicine" is not only, historically speaking, enveloped in mystery, but we find that the medicine-man revelled in mystery and his practice bristled with occultism, while, on the other hand, exponents of occultism found a happy hunting-ground in the field of medicine.

The evolution of the medical art is probably contemporaneous with the development of the higher anthropomorphic attributes in man. It cannot, of course, be doubted that instinct in the lower animals leads them to abstain from, or to safeguard themselves against, what might prove hurtful to their health, and instinct also leads them to seek out and to adopt what is likely to be beneficial. In a sense, therefore, we may allow that a kind of *preventive* medicine was in force previous to the evolution of man, but it may be safely surmised that *curative* medicine was not practised till man attained a certain degree of intellectuality and civilisation. Though the domestic animals in many instances show a marked appreciation of the medical and surgical aid they occasionally receive at the hands of man, we seek in vain

for any general evidence of initiative on their part in the practice of either medicine or surgery. An animal stricken with disease usually hides away in the nearest corner, and if the disease be a mortal one dies with more or less resignation. In some species his fellows, recognising his plight, will decide to put the victim out of his pain by a somewhat crude attempt at euthanasia. Preventive medicine in man, we may safely assume, therefore, preceded the evolution of the curative art and was coeval with the higher development of the reasoning faculty.

Medicine as a *profession* is probably older than the Church and the civil law—it certainly is older in superstitions, traditions, and ethics. The early tendency to the formation of associations and societies which is such a feature of to-day is found in the Asclepiadæ of Greece, the priest-doctors of ancient Egypt, the Lamas of Central Asia, the Vaidhyas of India, the Druids of ancient Britain, and the fraternities of the Middle Ages. In very early times, however, the profession of medicine was rarely practised alone and was usually combined with the priesthood; this combination was even continued so recently as the early and middle ages of Christendom, where the industrious monks were not only largely concerned with the production, maintenance, and dissemination of literature and science, but included within their ranks the doctors. The medical missionaries of to-day are the modern analogues of the priest-physician of old. They have the advantage, however, of carrying to distant climes an excellent system of ethics and a competent knowledge of the science and art of medicine, whereas the very mythological character of the ancient religions were bound to tincture the medicine of the superstitious doctor with that belief in the occult and mysterious which has always retarded the progress of medicine and of all knowledge. The general belief in the occult which is still fostered in most of us by the teachings of the nursery proves a powerful weapon now as formerly in the hands of the charlatan, the quack, the fortune-teller, the spiritualist, and the faith-healer—of all who make it their business to prey on a credulous public.

In the leading articles which will appear in many of the daily papers to-morrow you will probably find that practitioners of medicine are alluded to as "followers of Æsculapius" or as "students of the Æsculapian art"; these, and expressions of a similar kind, will naturally suggest to you that Æsculapius was the first personage who made any great reputation as a physician. Now, whether Æsculapius was a real man or merely a god of the usual mythological character is not quite clear. Hippocrates claimed to be the eighteenth in descent from Æsculapius, and this would seem to settle the point that he was really a man, but you must bear in mind that 2000 years before the Christian era the College of Heralds thought nothing of tracing a man's descent back to one of the gods, especially if his liberality in the matter of fees appeared to warrant such a pedigree. Not only is it not certain whether Æsculapius was a mythological personage from the start, or whether he was really a medical man and afterwards deified by the Greeks (who represented him as the son of Apollo), but there is equal uncertainty as to his nationality. He has been claimed as an Egyptian by birth, and he may well have been so, as in those days the Egyptians were a highly-learned nation, and Greece was early colonised by them, a compliment which the Greeks returned later. Certain it is, however, that the more intimate descendants of Æsculapius formed themselves into a priesthood, later known as the Asclepiadæ, and founded temples which had a three-fold character—they were at once places of worship, hospitals, and medical schools. Under their influence medicine became a regular profession, but in these early times internal medicine seems to have been kept distinct from surgery, the latter being usually combined with some trade, a condition which obtained even down to the last century, and the dissociation of surgery from the art of the priest-doctor may account for the undoubted fact that there has always been less occultism associated with surgery than with medicine. It is true that the dissociation of medicine and surgery was not universal, for it is alleged that Æsculapius had two sons who greatly distinguished themselves as physicians and surgeons at the siege of Troy in 1814 B.C. Whether these persons really acted as general practitioners or not is immaterial—there was no "double qualification" necessary in those days; but there is very clear evidence that many centuries before Hippocrates (who practised about 400 B.C.) the division of labour was so great that specialism was carried to the most ridiculous extremes by the Egyptians.

<sup>1</sup> Jastrow: "Fact and Fable in Psychology." Macmillan, 1901.

The priest-doctor was only allowed by law to practise one speciality. How many specialities the human body was then divided into I am not prepared to say, but every organ and every system apparently had its special exponent. We learn that those who treated fractured bones were not permitted to deal with diseases of the joints other than fractures; physicians for stomach complaints were by law debarred from treating diseases of the heart; again, a surgeon could not treat a patient with disease of the intestines, though he should have a first-rate knowledge of internal complaints. Fancy how galling it must have been to the surgeons of those days to have been obliged by law to hand over their cases of appendicitis to the physician whose speciality was the right iliac fossa. Again, picture an otologist who was not allowed under any pretext to insert his finger into the naso-pharynx of a deaf child—I am sure you cannot imagine what his feelings must have been. It is satisfactory to learn, however, that these specialists had to go through a regular medical curriculum which was not confined to their own special line of business; and the most gifted senior students were sent from Alexandria on a post-graduate trip to Heliopolis and other polyclinics in the same way that intending specialists go to Vienna and other places to-day. The medical men of Alexandria lived at Thebes in a quarter of their own just as consultants do here. Another pleasing feature, which has unfortunately no counterpart now, was that there would appear to have been actually enough staff appointments to go round, for each medical man, we learn, was attached to a hospital. When medical aid was required in private practice the messenger hastened not to the Harley-street area of Thebes where the specialists resided with their families, but hied him to the nearest hospital where the "Principal of the medical staff of the Sanctuary," as he was called, questioned the messenger as to the symptoms from which the patient was suffering, and he selected the man he thought entitled to the case. You may smile at this method of making a diagnosis without examining or seeing the patient and from a necessarily imperfect report of the symptoms, but it finds a parallel in the extraordinary and illogical mental attitude of so many of the laity at the present day. Laymen of a certain type see nothing ridiculous in undertaking without any medical knowledge to make a diagnosis of their own case and they either consult a quack institute by letter or else seek advice through the correspondence column of a newspaper, or prescribe for themselves a proprietary or "patent medicine" to be obtained at the nearest drug stores, "pouring drugs of which they know little into bodies of which they know less." Diagnosis is the part of medicine where accuracy can least be dispensed with—can least be arrived at in a haphazard and inexact way. Given an accurate diagnosis it is comparatively easy to get some idea of treatment from books, but treatment not based on reasoned diagnosis is valueless and sometimes far from harmless. There is an impression to-day—an impression often enough wrong, but one which we have little concern in correcting—that gratuitous medical services are rarely worth much, but the Alexandrian doctors took no fees from the patient. Their temples were maintained by a regular share of the State revenues, by gifts from kings, and by voluntary contributions from the laity. How Utopian this State-supported hospital system appears to us. Fancy St. Mary's Hospital receiving from the Revenue, instead of contributing to it!

I have remarked already that before the time of Hippocrates much of the materia medica and therapeutics of the priest-doctors was kept secret. This, in addition to curtailing our knowledge of their practice, must have not only retarded advance but encouraged the pernicious idea of mystery with which medicine was regarded by the laity. We can excuse this belief in a secret remedy in those who lived 4000 years ago when superstition was everywhere because medicine was practised by those who were also the exponents of a ridiculous theology, and when belief in the occult was universal, but it is, indeed, lamentable to see the most palpable forms of heterodoxy still receiving substantial support from all sorts and conditions of men, from the lord in his castle to the workman in his cottage.

Coming now to the earlier periods of Jewish history we find evidence that sanitary science and preventive medicine were in a more advanced state than the study and curative treatment of disease. The late Professor Sharpey used to delight in calling the attention of his students to the admirable system of public medicine enforced by that

great and wise man in Israel, whom he alluded to as his "excellent co-worker in the field of science," Moses. Moses was at once his own Minister of State for public medicine and chief medical officer of health, and doubtless he was assisted by an efficient staff of subordinates. We also find Moses figuring on emergency as a physician, but just as the mythical Æsculapius was always represented in statuary and carving as armed with a stick, around which a serpent was entwined, so when Moses was working miracles or practising faith-healing *en masse* in the wilderness we find him raising aloft the serpent, the symbol of office of the priest-physician. A *propos* of this, the belief in the miraculous power of rulers had its counterpart in modern times, for English sovereigns from the days of Edward the Confessor down to the time of Queen Anne regularly "touched" for the cure of the king's evil. The affair, however, does not appear to have always been a very disinterested one, as the patient's pocket was touched as well as his person. It is recorded that Charles the Second, of impious memory, made as much as £10,000 in one year out of this ridiculous practice. It is no wonder, then, that in those days every self-respecting practitioner with any confidence in himself laid claim to the performance of at least an occasional miracle, and this claim was often made with perfect sincerity. Our knowledge that the undoubted influence of the mind on the body and the influence of suggestion and expectant attention applies only to subjective states and functional disease enables us to understand why so many people in former days, on the principle that seeing is believing, were able to testify to miraculous cures within their own experience. It never occurred to them that there was an essential difference between functional and organic disease.

In the Bible the physician is with great frequency alluded to in a symbolic sense, but apart from these allusions there are distinct references to men who actually practised the art of medicine. Moses refers to the preparation of the sacred oil "after the apothecary's art," and Job, who may be excused for a certain amount of pessimism, spoke of his councillors as "physicians of no value." The Biblical references as a whole are nevertheless decidedly complimentary to the profession and in one instance embarrassingly so, for we are told of King Asa that when his disease was exceeding great he "sought not the Lord but his physicians."

The leading principle of the stupid homœopathy revived a hundred years ago, that "like cures like," was a mere reproduction of a very ancient medical aphorism. From the alleged fact that worms come out of the noses of sheep suffering from "staggers" or "turning fits" it was concluded that the larvæ of worms coming from the sheep's nose would be an effectual remedy in epilepsy in man, and as early as B.C. 560 Trallianus tells us that at two distinct utterances of the Oracle of Delphi these worms were recommended to be used by no less a patient than Democritus of Athens who suffered from epilepsy. You will be interested to know how the famous orator "used" the maggots. Like a sensible man, he did not eat them *au naturel* nor did he swallow them disguised as a bolus, but, being doubtless an unquestioning believer in amulets, he merely put the worms in a bag which he tied round his neck. Cure was, of course, unlikely. At the present day the homœopathic system is, medically speaking, exploded and discredited, but as a means of attracting the more credulous of the public its power is, if diminished, still considerable.

Passing now to Hippocrates, we find that he lived in the best and most prosperous period of Greek ascendancy. He was born in 460 B.C. and was the contemporary of such learned men as Socrates, Plato, Xenophon, Pindar, Thucydides, Æschylus, Euripides, Sophocles, Aristophanes, and Herodotus. He was a voluminous writer and codified the medical knowledge and traditions which had been handed down by the Asclepiads; he was not really the "father of medicine," as he is usually styled, but he was evidently, intellectually and practically, head and shoulders above his predecessors. One of his aphorisms, "*Vita brevis ars longa*," has passed into the ordinary speech and literature of all nations. I cannot better indicate what manner of man he was than by reading you the Oath of Hippocrates, and it will perhaps be more convenient to all present, not excluding myself, if I give it to you in English rather than at first hand in the language in which it was spoken and recorded.

I swear by Apollo the physician, by Æsculapius, by his daughters Hygieia and Panacea, and by all the gods and goddesses, that to the best of my power and judgment I will faithfully observe this oath and

obligation. The master that has instructed me in the art I will esteem as my parent, and supply, as occasion may require, with the comforts or necessities of life. His children I will regard as my own brothers; and if they desire to learn I will instruct them in the same art without any reward or obligations. The precepts, the explanations, or whatever else belongs to the art, I will communicate to my own children, to the children of my master, to such other pupils as have subscribed to the physician's oath, and to no other persons. My patients shall be treated by me to the best of my power and judgment in the most salutary manner, without any injury or violence; I will neither be prevailed upon by any other to administer pernicious physic, or to be the author of such advice myself. Cutting for the stone I will not meddle with, but leave it to the operators in that way. To whatsoever house I am sent for I will always make the patient's good my principal aim, avoiding as much as possible all voluntary injury and corruption. And whatever I hear or see in the course of a cure, or otherwise, relating to the affairs of life, nobody shall ever know it, for it ought to remain a secret. May I be prosperous in life and business and for ever honoured and esteemed by all men as I observe this solemn oath; and may the reverse of all this be my portion if I violate it and forswear myself.

You will observe the obligation under which he felt himself to be to his teacher—he even promised to provide him if necessary with the comforts of life; the sentiment is so admirable that on behalf of my colleagues and myself I would ask those of you who are prepared to take the Oath of Hippocrates to remember the professional support which this master in medicine swore to render to his former teacher. Again, he had some sense of professional etiquette. Although he makes no allusion to what he would do in intussusception, yet he is prepared to leave a small field absolutely in the hands of the surgeons; cutting for stone he will even “not meddle with, but will leave it to the operators in that way.” There is, however, here a covert suggestion of “meddlesome” surgery. The sentence in which he promises professional secrecy in reference to whatever he “might hear or see in the course of a cure or otherwise” is specially interesting as showing that he set out as no charlatan promising to cure everybody. He clearly anticipated that some of his results, like ours of to-day, would be “otherwise”; in fact, in spite of his pre-eminence over his fellows, his knowledge of anatomy and physiology was so crude and his pathology so humorous that we might wonder that the founder of the Humoral System of pathology had any results which were not more or less “otherwise.” I will not detain you with an account of the erroneous notions which Hippocrates held in normal and morbid anatomy, but the explanation is simple: owing to extreme reverence which the Greeks had for the dead he was absolutely debarred from learning anything by anatomical dissections and post-mortem examinations. His knowledge of anatomy in health and disease was derived from the writings of those of his predecessors who had occasionally availed themselves of opportunities for actual dissection. His acumen, however, as a clinical observer of the course and symptoms of disease was of a very high order. He founded his views on facts when facts were at hand, and so far his observations on diet, on climate, on expectant treatment, and on the *vis medicatrix nature* combined with good nursing, are not unworthy of perusal to-day; but it was when, relying on the records of others, he dealt with what he supposed to be facts, that he gave way to that free play of the imagination which resulted in his system of humoral pathology. Whilst essentially a clinical observer Hippocrates seems to have employed a number of drugs in use at the present day—and his materia medica was extensive if peculiar. He frequently employed venesection. He was a believer in the theory of opposites which shows that he was no homeopathist. Hippocrates, however, with all his knowledge had his superstitions—he believed in “critical days.”

Herodicus, a contemporary of Hippocrates, was the first to adopt gymnastic exercises in the treatment and cure of disease, and we have here the beginning of movement cures and similar therapeutic measures which have attained great popularity and some distinct success at the present day. These, like everything else, have been outrageously quacked; and as an instance I may mention the case of a patient of mine who was induced by one of her titled and fashionable friends to go to a Swedish masseur who held a diploma in his own country; and this charlatan promised to “disperse” a sebaceous cyst of the scalp by a course of movement treatment. I think that you will agree with me that if he had succeeded in doing so he would have well earned the mere matter of £100 which was the fee asked. A suggestion that payment should be made on dispersal of the tumour, and not in advance, led to the abandonment of this interesting course of treatment.

About 300 B.C. Philenus founded the School of “Empirics”;

anatomy and physiology were dismissed as useless, and in the treatment of disease experience and observation alone were depended upon. The Empirics rejected the doctrine of occult causes of disease as taught by Hippocrates, though this doctrine was adopted later by the Dogmatics. Aristotle, who was born in 384 B.C., began his medical studies well—i.e., by actual dissections on the cadaver and on the lower animals, and he was really the founder of comparative anatomy. As every schoolboy knows, he later elaborated a system of philosophy, which was plausible, comprehensive, and mostly absurd; by amalgamating his philosophy with the medical teaching of Hippocrates he not only succeeded in founding the School of Dogmatics, but added materially to the retardation of medical progress during the next 1000 years.

Soon after the Christian era the more prominent physicians of all sects and factions came together in an agreement that no one sect contained all the truth. Under the title of the Eclectic School they claimed to select all that was good and useful and to reject all else. I will not weary you with the names of those who brought this school into prominence, but I must mention one of them—Cleombrotus—for he holds a record, which, I believe, stands to-day: he received a fee of 100 talents, a matter of £15,000, for curing King Antiochus of a dangerous disorder. Apart from this the Eclectics seem to have been a failure.

When one considers the high position attained by literature, the lofty standard reached in poetry and the drama, and the super-excellence of the Greeks in sculpture, painting, and architecture, it is a matter for much wonder that such slow progress was made in medical science. Even in anatomy, where there was a concrete basis and well-defined sphere of research, the advance of knowledge was tardy; the historians gravely record how this or that membrane was detected, or when certain bones were distinguished and named, just as the astronomer tells us that in this or that year a planet was discovered. Physiology and chemistry as exact sciences could scarcely claim to exist.

Turning from the Greeks to the Romans, the first Latin writer of any celebrity was Cornelius Celsus, who flourished about the commencement of the Christian era; he has given us a valuable summary of the medical practice of his time. There seems some doubt, however, as to whether he ever really practised the medical art. It was not until the time of Claudius Galen (born A.D. 131) that medicine arrived at the stage of puberty. His researches on anatomy, physiology, pathology, chemistry, and, in fact, every department of medicine, were published in no less than 500 treatises, only some of which are now extant. In anatomy he was the first to describe the popliteus, the platysma myoides, the sterno-hyoid, and many other muscles. He seems, however, to have been much better up in anatomy than physiology, for we find him attributing the essential phenomena of life to certain “occult forces” inherent in the several organs; these forces, the vital, the animal, and the natural, he located in the heart, brain, and liver respectively. Galen's leading dictum was that “health is maintained by supplying similar with similar, whilst disease is overcome by opposing contraries to contraries.” The plan of treatment in Galen's time mostly consisted in giving particular remedies for particular diseases—specific treatment, in fact. Even Galen, you see, could not get away entirely from a system, and when he and his contemporaries speak of a rational system of therapeutics they do not attach the same interpretation to the word “rational” that we due to-day; they believed in specifics yet they had little knowledge of those diseases which are now known to be really due to specific causes—e.g., those of microbic origin. To-day a large number of even the educated public take much the same view that diseases are little more than ideas, occult forces in various organs, diagnosable without skill, and readily “dispersed” by advertised specifics or by various occult methods.

Time does not admit of my tracing the vicissitudes of medicine through the dark ages. It reached its lowest ebb in the seventh century when Mahomedanism invaded Europe. In mediæval times necromancy was rampant, and even Roger Bacon, who flourished in the twelfth century and is spoken of as the founder of experimental science, could not shake off the illusions of astrology and alchemy. The sixteenth century was the age of epidemics and, of course, of quacks, for it is in periods of emotional excitement that people will, literally and metaphorically, swallow anything. In more recent times waves of occultism have been marked by the

appearance of mesmerism, homœopathy, spiritualism, theosophy, and, lastly, various forms of faith-healing, with Christian Science at the summit of this bad eminence.

Christian Science cannot be dismissed without some examination in one of its aspects. I remember a recent conversation with an earnest believer in faith-healing who was convinced that his family when sick would be much better treated and would get much better results from his own peculiar system of therapeutics than from ordinary medical practice; and after listening patiently to my arguments, which were directed to demonstrate that a belief in such a system was a return to the occultism of mediæval times, he asked me the very pertinent question, whether I and the bulk of medical men did not encourage, or at all events countenance, not only prayers for the sick but prayers by the sick, as a real and material aid in the treatment of disease; and when I replied that *in a sense* it might be so he demanded that I should explain how a belief in the possible interposition of God in altering the course of disease could be regarded as anything less than a belief in the miraculous and the occult—a belief in something just as miraculous as would be the altering of the stars in their courses. He proceeded to condemn medical men as themselves believing in and countenancing the occult in medicine whilst they reprobated the doctrine of occultism as practised by others outside their own narrow ring, and he pointed out that until medical men had extracted the beam from their own eye they were scarcely competent to deal with the obliquity of vision of those who were in competition with them. We must face an argument of this sort—it is rather an accusation than an argument—which is freely levelled against us when we denounce the fads of the present day which come within the province of the miraculous and occult. The question is, Do medical men believe in prayer as a therapeutic agent? If those in this room who believed generally in prayer were asked to stand up it is probable that there would not be many, if any, left seated. The moral and intellectual gain which accrues from that earnest introspective meditation and examination which is an essential process in efficient prayer can be productive of nothing but good if rightly exercised. If asked, however, whether you believed in the efficiency of prayer in altering for the better the progress of real bodily disease it is probable that in this mixed audience many would prefer not to give a plain answer of yes or no. We all know what our mothers would reply, or would have replied to this question, for did they not in their simple faith instil into us the efficacy of prayer under all circumstances? This doctrine, though admirable in the cramped environment of the nursery, has, I imagine, appeared to require modification with the expansion of our physical and mental horizon. The specific question is, Can a *supernatural* effect result from prayer under any circumstances in the course of sickness? If we are unable to face this question we are unable to face the Christian Scientists and faith-healers. The question has been put to me again and again in discussing this subject during the last 12 months. My answer is this, that so far as I know, prayer as an agent in the treatment of organic disease is neither taught nor even alluded to in the teaching of medical men of the present day. It is not mentioned in our treatises on medicine, it is not alluded to in the class-room or lecture theatre, it has no medical place in the wards. It is quite unlikely that there would be a conspiracy of silence on such an important matter, for if we believed even in the occasional possibility of Divine intervention, and were treating a case of, say, tuberculosis of the larynx, it would be the first therapeutic agent adopted rather than the last. I know that some timid folk will think I am treading on dangerous ground in raising the question of what is the truth in this matter. Divine healing to-day is neither taught by, nor known to, the orthodox medical profession. I am not aware that it is an article of faith absolutely demanded by the Church, though it is doubtless held as a "pious opinion," and possibly taught, in some quarters by worthy persons; but it is an opinion which the bulk of the orthodox medical profession could only accept after overwhelming evidence. Is there any evidence? The fact is, religion and theology have nothing to do with medicine, and that is the strongest and shortest answer to the Christian Scientists. One is asked why a large number of medical men go yearly to St. Paul's under the auspices of the Guild of St. Luke the Physician. They go, of course, because they belong to the Christian faith, but their going does not imply any narrow

theology. Theology has no more to do with medical science than it has to do with mathematics, or, to put the matter more concretely, it has no more to do with a vesical calculus than it has to do with the differential calculus.

We must allow in the most generous manner the enormous indebtedness of medicine in the past to the various religious orders which fostered it, but the partnership has persistently suffered from the defects of its qualities; there has always been, both in modern times and in the age of paganism, too much of the superstitious encumbrances of religion engrafted on medicine; medicine has been inoculated and impregnated with the least defensible pretensions of religion. The calling of the priest and the medical man are now usually practised separately, and rightly so, as they are essentially distinct, and we must now admit unreservedly that all physical science, and therefore medical science, has, from a *practical* point of view, nothing whatever to do with theological beliefs. I know that I may be thought to be going beyond the teaching of Herbert Spencer, who has devoted some space in his "First Principles" to the examination of the question whether there is not some common region in knowledge where science and religion meet; but I am afraid that you will find little comfort or illumination from Spencer's conclusion, which is that ultimate religious ideas and ultimate scientific ideas, if pursued far enough, will be found to arrive at the stage where the most certain of all facts will be that "the Power which the universe manifests to us is inscrutable"; in other words, that the researches of science and the speculations of religion ultimately lead to a veritable *terra incognita* where is nothing but the Unknown and the Unknowable. Lest you may think that I am retailing doctrines dangerous to young men who have just left a public school which should render those subscribing to them outside the pale of the Christian Church, let me read you an extract from a lecture delivered some years ago on behalf of the Christian Evidence Society by a former Regius Professor of Divinity at Oxford, Dr. Payne Smith. Speaking of the then current antagonism between religion and science he says:—

And first, revelation has nothing to do with our physical state. Reason is quite sufficient to teach us all those sanitary laws by which our bodies will be maintained in healthful vigour. If the Bible condemns drunkenness, gluttony, and the like it does so not for sanitary reasons but for moral reasons because they are sins. So revelation has nothing to do with our mental powers; whatever we can attain to by our mental powers we are to attain by them. Physical and metaphysical science alike lie remote from the object matter of revelation. Because God has, in the Bible, given us revelation in an informal way, in order, perhaps, to commend it to our entire nature, people often forget that its proper object matter is simply the moral relation in which man stands to God, especially with reference to a future state of being. Religious men forget this, they often take up an antagonistic position to science, and try to make out systems of geology and astronomy and anthropology from the Bible, and by these judge all that scientific men say. Really the Bible never gives us any scientific knowledge in a scientific way. If it did it would be leaving its own proper domain.

If time had permitted I should have liked to have dealt with some forms of present-day quackery—e.g., bogus institutes for the deaf and the sale of expensive ear-drums and other forms of aural humbug which I have had special opportunities of becoming acquainted with.

I may be expected to draw some moral from this necessarily imperfect sketch relating mostly to the seamy side of medicine. Will the spread of education render the general mass of the people, especially those particularised by Carlyle, more capable of distinguishing between fact and fable in psychology? Will it render them less gullible and less liable to be led away by waves of emotional heterodoxy? I confess that I am not very sanguine on this point, for what are termed the educated classes are amongst the worst offenders. Will the educating of the youth of the country in the elementary facts of physiology, in the laws of health, and in the principles of observation and reasoning aid us much? Again I am not sure, for we know the proverbial danger of a little knowledge. I think that something, however, can be done by the healthy and active influence of members of the medical profession working individually and seizing every opportunity of instructing individual members of the laity on points concerning which they are liable to form and hold false views. To take a specific example, small-pox is now very much in the air. How shall we overcome the prejudices of that well-meaning but dangerous person the "conscientious objector" to vaccination? We must first make ourselves acquainted, not only with the history and facts of the subject, but we must carefully study the standpoint of

our opponent, and then by friendly argument, by the loan of literature, and such means, endeavour to induce him to look at the matter, even if only for a few minutes, from our point of view. These educational means, which have been unostentatiously worked in the past, require to be pushed with extra vigour by all of us in the future if we are to make further headway against heterodoxy, quackery, and occultism.

#### ABSTRACT OF

### An Address

ON

## THE PRESENT TREATMENT OF INOPERABLE CANCER.

*Delivered before the West London Medico-Chirurgical Society on Oct. 4th, at the Opening of the Session 1901-1902,*

By ALFRED COOPER, F.R.C.S. ENG.,  
PRESIDENT OF THE SOCIETY.

GENTLEMEN,—The honour which you have done me by electing me as your president is one of the greatest honours which I have yet received, for, although the West London Medico-Chirurgical Society is young in years, it is, I believe, by far the most active in its work and growth of all the other medical societies in London. On taking the chair for the first time I have thought that I cannot do better than draw your attention to a consideration of the present treatment of inoperable cancer, a disease which has attacked the highest in the land and which is certainly becoming more prevalent.

It is unnecessary for me as a surgeon to state that in cases where the disease together with the enlarged lymphatic glands are in such a position that their removal can be effected without too great a risk to life, this should be done thoroughly and at once, and that no valuable time should be wasted in trying any suggested cancer cures. It is in the cases of so-called inoperable disease that it is not only justifiable but also wise to try these new remedies, since a patient with recurrent cancer will be only too glad to run any risk or to undergo any discomfort which gives the slightest chance of relief. During the last decade attention has been drawn by several distinguished surgeons to a number of methods of treatment as follows, and I will briefly give you the information which I have been able to collect on the subject: (1) inoculation with the streptococcus of erysipelas; (2) subcutaneous injection of Coley's fluid; (3) subcutaneous injection of anti-cancerous serum; (4) oöphorectomy; (5) thyroid feeding; (6) lymph gland extract; (7) treatment by Roentgen rays and by Finsen's light; (8) injection of various irritating substances and the production of aseptic suppuration; (9) electricity; and (10) drugs. When considering what benefit has been derived from any particular method of treatment, it must, however, be borne in mind that different forms of malignant disease behave in a manner peculiar to each growth, and that some of the atrophic forms of cancer of the breast have been known to diminish and even to disappear spontaneously.

#### INOCULATION WITH THE STREPTOCOCCUS OF ERYSIPELAS.

Nearly 200 years ago it was observed that a certain number of malignant growths disappeared after an attack of erysipelas, and attention has recently been drawn to the subject by Fehliessen and Billroth, who have reported cases of inoperable sarcoma cured by an attack of erysipelas. After the discovery of the streptococcus Fehliessen suggested that an inoculation of a cultivation of the organism might be used to produce a like result; he succeeded five times in producing erysipelas by inoculations of pure cultures of streptococcus in patients suffering from malignant tumour. He obtained a cure in a case of cancer of the breast, and in four other cases there was temporary atrophy of the tumour.

#### SUBCUTANEOUS INJECTION OF COLEY'S FLUID.

No satisfactory fluid was, however, obtained until Coley of New York introduced the use of the mixed toxins of the streptococcus of erysipelas and the bacillus prodigiosus.

The preparation of the fluid was based on the discovery of Professor Roger of Paris, who found that the addition of a non-pathogenic micro-organism—the bacillus prodigiosus—to cultures of certain pathogenic micro-organisms, greatly enhanced the virulence of the latter, and among these organisms was the streptococcus of erysipelas. At first Coley mixed together the most virulent streptococcus cultures obtainable with that of the bacillus prodigiosus in the proportion of four of the former to one of the latter, sterilising the mixture by filtration, and preserving it by the addition of a little thymol. He now, however, makes the fluid by inoculating peptonised bouillon from the colonies obtained by passing the micro-organism of a fatal case of erysipelas through a rabbit's ear. The growth of the germ is then carried on for three weeks at a temperature of from 30° to 35° C., after which the flask is inoculated with the bacillus prodigiosus. The fluid is then exposed to a room temperature for 10 days, when, after being thoroughly shaken, the cultures are transferred to small sterilised glass-stoppered bottles, and sterilisation is ensured by exposing these to a temperature of 60° C. for an hour. The injections are made into the substance of the tumour itself, and the rule is to begin with a minimum dose and slowly to increase each day until the desired action is obtained. Toxins produced from very virulent cultures, mixed and unfiltered, should never be given in larger initial doses than half a minim, boiled water being added to obtain dilution. Each day the dose should be increased by half a minim until the reaction temperature reaches 102° or 103° F. The amount required to produce a feeling of chill, and a temperature of 102°, varies with the individual case, but one or two minims will generally be sufficient. The effects of the injection are rather unpleasant, nausea and vomiting frequently occurring after severe reactions, and after slight reactions, headache, muscular pains, especially in the back, and a feeling of general malaise. If no beneficial results are apparent after three weeks' treatment Coley believes that it is useless to continue the injections, since in nearly all of his successful cases marked improvement was seen within a week of the first injection. When apparent benefit results from the treatment and there is no contrary indication to its continuance it may be kept up for four months, with occasional intervals of rest. Coley has used the fluid in 148 cases, and out of these 24, or 15 per cent., improved. Six of these cases afterwards recurred, but the remaining 12 per cent. were permanent successes, some of the cases having remained well for six years. Coley has also collected 35 cases treated by other surgeons; out of these cases in 26 the tumour disappeared completely. Most of these cases had been diagnosed as sarcoma by both clinical and microscopic examination. Two cases were reported by Moullin in which death occurred in consequence of the injections. In the first case the patient was a man of about 70 years of age with a large vascular tumour of the femur; the other died from pyæmia. It was found that the greatest chance of improvement was in spindle-celled or mixed-celled sarcoma. Coley himself considers the results in carcinoma to be unsatisfactory.

#### SUBCUTANEOUS INJECTION OF ANTI-CANCEROUS SERUM.

Last year Vlaieff introduced in Paris a method of treatment of advanced malignant disease by inoculation with a special anti-cancerous serum. He stated that he obtained from malignant tumours certain parasitic cells, called blastomycetes, which had the power of producing abdominal cancer in guinea-pigs when inoculated into the peritoneum. Having done this he endeavoured to immunise several different animals, but he only succeeded in getting an active serum from pigeons, fowls, and geese. This latter serum inoculated into rats prevented the development of cancer after subsequent inoculations with the blastomycetes. In man he inoculates 10 cubic centimetres of serum obtained from geese, and the dose, though considered free from any danger, produces a considerable local and general reaction. Vlaieff states that he has treated 60 cases of human carcinoma by this method. When it was administered early, before ulceration and glandular enlargement, the serum was capable of exercising a curative effect.

#### OÖPHORECTOMY.

The treatment of inoperable cancer of the breast by oöphorectomy is one of the most interesting subjects brought forward during the last few years. Much of our knowledge of the subject we owe to Mr. Stanley Boyd, from whose paper in the *British Medical Journal* I have freely drawn in

the following remarks. The first operation of the kind was performed by Dr. G. T. Beatson, of Glasgow, in 1896, and, although the patient was suffering from a large recurrent and inoperable growth of the breast, eight months after the operation all trace of the disease had gone. She died, however, from a recurrence nearly four years later. According to Mr. Boyd, Dr. Beatson was led to consider that oöphorectomy would be useful in treatment of inoperable cancer of the breast by the following consideration: "In lactation there is rapid multiplication of mammary epithelium; the cells undergo fatty degeneration as fast as they are formed, break down, fall into the lumina of the gland acini, and come away in the milk. Beatson learnt that certain farmers spayed lactating cows in order to maintain permanently or for a long time the above state of matters, resulting in the secretion of milk. In cancer also the mammary epithelium multiplies rapidly, but, instead of undergoing fatty degeneration and being cast off, it distends the acini, penetrates into the lymph spaces of the breast, and there, floating in a nutrient fluid, it continues multiplying and forcing its way onwards towards the lymphatic glands. As oöphorectomy in the cow maintains fatty degeneration of the epithelium of the lactating breast, Beatson thought that it might induce fatty degeneration of the epithelium of the cancerous breast. Accepting menstruation as the evidence of ovarian activity, Beatson was inclined to believe that the cessation of lactation was due to the re-establishment of the influence of the ovaries, which influence had been suspended by the gravid uterus, and thus removal of the ovaries resulted in the indefinite continuance of lactation. It further occurred to him as possible that cancer of the mamma might actually be due to some 'ovarian irritation' or to 'some defective steps in the cycle of ovarian changes,' and that removal of the ovaries might bring cancerous cell-proliferation to a standstill or induce fatty degeneration of the cells as seen in lactation." About the same time that Dr. Beatson reported his first case, Mr. Pearce Gould showed a woman who, six months before, had been apparently moribund with secondary cancer in the breast, in the supra-clavicular glands, in the right lung, and in the femur, and in whom without any treatment the cancer began to disappear, the menopause having occurred a year previously. Three years later she was in good health and free from disease. Mr. Boyd last year collected 54 cases of oöphorectomy for cancer, which were in no way selected cases, but included the whole experience of several surgeons. As a conclusion, he considers that on an average life was prolonged six months by the operation. Out of the 54 cases, 19, or 35 per cent., were more or less markedly benefited by the operation, and only one died. Mr. Boyd thinks that oöphorectomy should be offered in all cases, other than the very acute, of inoperable mammary cancer in women over 40 years with no visceral or bony lesions, and before the menopause. Cancer in other parts of the body, even in the uterus, is quite unaffected by oöphorectomy.

#### THYROID FEEDING.

The treatment of inoperable cancer by thyroid feeding is also due to Dr. Beatson, who considers that the so-called cancer bodies are not parasites but are cells undergoing mucoid degeneration, and he therefore thought that a free administration of thyroid extract might influence them greatly and in time effect a cure. Dr. Beatson employed the treatment in three cases; but in two of these it was associated with oöphorectomy, so that the improvement noticed was probably due to that cause; in the only case in which thyroid extract alone was given no improvement followed. Soon after this Dr. Frederick Page of Newcastle reported the case of a woman from whom he had removed a tumour of the breast and who within a few months developed a large and inoperable recurrence. Thyroid feeding was commenced with three-grain doses, and this was increased till 15 grains of the extract were given thrice daily, and at the end of 18 months the tumour had disappeared. It is interesting to observe that a fresh nodule of recurrent growth appeared during treatment. A further report of the case states that six months later the growth had commenced to increase and was quite unaffected by thyroid feeding. Another physician, Dr. R. Bell of Glasgow, was favourably impressed with the use of thyroid feeding and tried it in two cases of epithelioma of the cervix, and states that he obtained satisfactory results. Mr. H. T. Butlin, on the other hand, tried it in a good many cases, but has not obtained even temporary benefit in a single case. It should be noted that the favourable cases have been carcinoma of the breast, and there is no evidence

that the treatment can be of any service in carcinoma of other parts.

#### LYMPH GLAND EXTRACT.

Somewhat analogous to thyroid feeding is the treatment by means of freshly-prepared lymph gland extract which has been recommended by Dr. H. Snow. Four grains of the extract are given in capsules, one being taken after each meal. Dr. Snow states that he has used this treatment in several cases of mammary cancer and that it resulted in considerable improvement.

#### TREATMENT BY ROENTGEN RAYS AND BY FINSSEN'S LIGHT.

Several cases of rodent ulcer have been treated in the West London Hospital by means of exposure to x rays. Although they can scarcely be classified under the heading of inoperable cancer, still they have a distinct bearing on the subject. In applying the treatment the surrounding parts of the face, especially the eyes, are protected by means of a lead mask and a vacuum tube connected with a coil giving a 10-inch or a 12-inch spark is used. The vacuum tube is placed about five inches from the ulcer and an exposure is given daily for from 10 to 15 minutes. The ulcer is usually healed after about a month or six weeks. A few months ago Mr. Andrew Clark recorded a case of chronic cancer of the breast which was treated by x rays. The patient was a woman, aged 60 years, who had noticed a lump in the breast for nearly seven years. She had declined operative treatment and the lump had grown and ulcerated till the whole breast was replaced by a large ulcer. There were enlarged glands in the axilla. The x rays were applied five days a week for 15 minutes each day and at the end of two months the general condition had improved, the pain had lessened, the ulcer had cleaned and become smaller, and the axillary glands were getting less. This, as far as I can find, is the only case of cancer of the breast treated by the x rays, and it must be noted that it was of a very chronic type, its behaviour being more like a rodent ulcer than a scirrhus. The action of the x rays is almost similar to that of Finsen's light treatment, and several cases of rodent ulcer have been treated by that method; the treatment, however, is more painful than that by the x rays, and does not possess any advantages. Too few cases have been treated by either method to form any definite conclusion.

#### INJECTIONS OF VARIOUS IRRITATING SUBSTANCES.

Under this heading are included a number of rather diverse methods, the action of most of which is to excite inflammation in the tumour. Among these are (1) the parenchymatous injection of acetic acid; (2) the parenchymatous injection of alcohol; (3) the parenchymatous injection of methyl violet; (4) the parenchymatous injection of the venom of the cobra di capello; and (5) artificially produced suppuration, either (a) by oil of turpentine, (b) by arsenious acid, or (c) by calcium carbide.

*Parenchymatous injection of acetic acid.*—More than 30 years ago, in 1866, my attention was drawn by Sir William (then Dr.) Broadbent to the method of treating inoperable cancer by the parenchymatous injection of acetic acid. The injection must be made slowly, and Sir William Broadbent lays stress on a large quantity of a weak solution, as much as 80 minims, being preferable to a smaller quantity of a strong one. He employed the strong acetic acid of the British Pharmacopœia, diluted with three or four parts of water. A great number of injections have to be made and in some cases they were repeated daily. It was not claimed for this method that it was curative, but that it prolonged life and rendered the patient's suffering less severe. Sir William Broadbent treated some cases of recurrent cancer of the breast with very satisfactory results, the tumour being cast off in large fragments and the enlargement of the axillary glands subsiding. He also treated a case of cancer of the rectum producing obstruction of the bowel, in which the growth was much reduced in size and the obstruction relieved. About the same time, too, at his suggestion, I treated a case of cancer of the rectum. The patient died from exhaustion some little time afterwards and at the necropsy it was found that the tumour of the rectum had entirely disappeared, but that the liver and other abdominal organs were extensively affected by cancer. I also used this method in the case of a labourer who was sent to me from the country suffering from a large epithelioma on the back of one hand. I injected acetic acid (1 in 7) into the growth and repeated the injection once a week for six months. The growth entirely disappeared

under treatment and the patient was so pleased with the result that he indulged in several drinking bouts; unfortunately one of them took place on the day on which I had arranged to show him at the Medical Society of London and on his way to the railway station he fell into a pond and was drowned. The friends refused to let me have the hand.

**Parenchymatous injection of alcohol.**—This was first advocated by Schwalbe and Hasse in 1872. The latter surgeon has treated 20 cases of cancer by this method but has had only one successful case, a naso-pharyngeal cancer, and even in this case a large gland was left. According to another observer 15 cases of cancer of the breast out of 18 were cured. A 30 per cent. solution of alcohol was used at first, the strength being gradually increased to 40 or 50 per cent. The amount used in each injection varied from two to 10 cubic centimetres, and an injection was made every third or fourth day.

**Parenchymatous injection of methyl violet.**—Von Maestig Moorhof introduced the treatment of inoperable cancer by injections into the substance of the tumour of a solution of methyl violet. Watery solution (1 in 500) was used, and from three to six grammes of this were injected at short intervals. In several cases considerable shrinkage of the growth occurred. This treatment has been tried in the West London Hospital without producing any benefit. It is not so painful as the injection of alcohol. I have been unable to find any evidence of a cure following the treatment.

**Parenchymatous injection of the venom of the cobra di capello.**—The dry venom of the cobra di capello was employed by Répin in doses of one-fortieth of a milligramme, injected hypodermically. This dose was gradually increased to seven milligrammes. This patient's weight increased, but there was no alteration in the tumour, the injections producing painful sensations similar to those following the streptococcus toxin. It is not likely that any further experiments will be made with this remedy, as it is both painful and dangerous.

**Artificially produced suppuration, either (a) by oil of turpentine, (b) by arsenious acid, or (c) by calcium carbide.**—Czynski treated some cases of advanced carcinoma by producing suppuration of an aseptic character. He employed injection of oil of turpentine, and although much necrotic tissue was thrown off and suppuration was well established the advance of the disease was in no way checked. The injections, too, inflicted considerable suffering on the patient. On the other hand, Wurth records a case of sarcoma of the abdominal wall treated by injections of arsenious acid into isolated areas of the growth. After a short time profuse suppuration occurred and the treatment was abandoned. The suppuration continued for several weeks, when it gradually ceased and the tumour disappeared. Up to ten years afterwards there was no recurrence. Carbide of calcium in the presence of water produces acetylene gas, and Etheridge of Chicago has employed it in cases of carcinoma of the uterus in the following manner. The organ is first thoroughly curetted, the hæmorrhage being checked by the actual cautery. After being made as dry as possible a piece of calcium carbide of the size of the thumb is placed in the cavity of the uterus, which is then firmly packed by iodoform gauze. Acetylene gas is at once evolved, which produces a large amount of froth. The patient is kept in bed for three days, when the dressing is removed and a fresh piece of calcium carbide is inserted. After a series of such applications a clean, simple ulcer remains. In two cases a cure was obtained by this method, but at present its application has been too limited to warrant any opinion being formed of its value.

#### ELECTRICITY.

There are several different methods in which electricity can be employed in the treatment of cancer. Inglis Parsons has treated several by means of currents having a high electro-motive force, the current being flashed instantaneously a number of times through the tumour. The patient is anaesthetised and insulated needles are placed into the tumour some inches apart. The current is obtained from 70 cells and has an electro-motive force of 105 volts. He commences with a current of 10 milliampères and increases it to as much as 600 milliampères, the application being instantaneous and being repeated about 50 times. Although some of Dr. Parsons's cases improved they were, however, of the class which could have been treated quicker and more certainly by operation, and one patient at least died from the shock of the use of too strong a current.

Reading of Philadelphia has reported three cases of advanced cancer successfully treated by frequent and long-continued electric punctures, a current of from 15 to 20 milliampères being used for about 10 minutes at each application. The disadvantages of this treatment are the pain and the duration. The term "kataphoresis" has been applied to the treatment by means of a strong current, in which a zinc electrode heavily coated with mercury is placed in the tumour while the negative pole is connected with another part of the body. Massey employed this treatment and believes that the oxychloride of mercury has a selective action on cancer cells. He found cocaine anaesthesia sufficient to allay the pain, so long as the current was not stronger than 150 milliampères, but as in other cases he uses currents of 500 milliampères he recommends general anaesthesia. In eight cases treated by this method improvement was seen in all. The objection to the method is the necessity for frequent and long-continued treatment and its uselessness where the lymphatic glands are involved.

#### DRUGS.

*Chelidonium majus* (celandine) enjoys a great reputation in the East Indies for the treatment of cancer, and was first recommended in Europe 30 years ago. Attention has recently been drawn to it by the publications of Dennisio and other Russian physicians, and an excellent *résumé* of the work of these physicians appears in an article in the *Therapeutico Gazette* by Spirak. Dennisio gives half a grain of the extract in peppermint water, increasing the dose to five grains in the 24 hours. If given hypodermically, the extract is diluted with distilled water, and one cubic centimetre is injected not oftener than once a week. Spirak has collected 61 cases treated by 14 different surgeons in this way; of these 33 showed improvement and 27 did not. Great benefit follows the exhibition of large and increasing doses of morphia in hopeless cases. The drug should be pushed without any scruple, and it is quite immaterial how large an amount is taken at the end; it is quite common to give several grains of morphia each day.

As a result of this review of the different remedies which have been recommended we may, I think, arrive at the following conclusions:—

1. That in cases of inoperable sarcoma, more especially the spindle-cell variety, the patient should have the option of Coley's fluid given to him, since a certain number of cases have been cured.
2. That in cases of inoperable cancer of the breast in women of about 40 years of age in whom the menopause has not occurred the operation of oöphorectomy should be proposed, and this treatment may be combined with thyroid feeding.
3. That in cases of inoperable rodent ulcer and in the superficial malignant ulceration in other parts the Roentgen rays give a good hope of improvement.
4. That in cases where these other methods are declined or are inapplicable the internal administration of celandine is worthy of trial, and when the case appears quite hopeless morphia should be pushed without hesitation.
5. Finally, I would suggest that before trying any of these remedies the risk should be fully pointed out to the patient, that the faint hope that most of them afford should not be magnified, and that the discomfort of treatment should be fully discussed; in fact, the surgeon should not do more than offer the treatment and leave the person to accept or receive it.

In conclusion, I should like to express my thanks to my friend Mr. L. A. Bidwell for the able assistance he has given me in investigating this subject. I have also to express the sense of loss which the society has suffered in the removal by death of Dr. J. L. W. Thudichum. Dr. Thudichum was one of our earliest Presidents, and had always taken the very deepest interest in the society's welfare. His geniality and consideration for others endeared him to everyone who knew him, and his enthusiasm and deep store of knowledge made him respected by all.

**PREVENTION OF TUBERCULOSIS.**—At the meeting of the Exeter City Council held on Oct. 2nd it was decided to invite the medical profession of Exeter to notify all cases of pulmonary tuberculosis under treatment by them for one year and that the usual fees should be paid as for cases under the Infectious Diseases Notification Act. It was further determined that the sanitary inspector should visit all such cases and should offer his services for disinfection, &c.

# RECENT DISCOVERIES IN CENTRAL AMERICA PROVING THE PRE-COLUMBIAN EXISTENCE OF SYPHILIS IN THE NEW WORLD.

By THOMAS GANN, M.R.C.S. ENG., L.R.C.P. LOND., J.P.,  
DISTRICT SURGEON, COMOZAL, BRITISH HONDURAS.

SINCE the first recognition of the various symptoms of syphilis as phases of a single specific disorder which took place in the closing years of the fifteenth century two points in its history have provoked no small amount of controversy, alike amongst physicians and antiquaries; firstly, did syphilis exist in America before the discovery of that continent by Christobal Colon? and, secondly, was syphilis introduced from the New to the Old World?

I propose in this paper, after giving a short account of the early history of syphilis and the various causes supposed to have given rise to it, to describe the contents of an ancient Indian mound opened by me a short time ago in Honduras which supply circumstantial evidence so strong as almost to amount to proof positive of the pre-Columbian existence of syphilis in America, and this point once proved the probabilities are, it must be apparent, strongly in favour of the disease having been first introduced into the Old World from the New. That various forms of venereal disease were prevalent in the East, especially in China and India, centuries before the discovery of America is a fact not to be denied, but the descriptions handed down to us are so vague, fragmentary, and disconnected that it is impossible to recognise from them the exact nature of the disease. On its first recognition as a specific disease the opinions of contemporary physicians as to its origin were varied and marvellous; thus, Corradino Gillini and Gaspare Torella, two of the first physicians of their day, believed that the disease arose from the near conjunctions of the sun with Jupiter, Saturn, and Mercury, in the sign of Libra, which took place in the year 1483. Nicolaus Leoniceus, in his "Opus de Morbo Gallico," attributes it to the abundant rainfall in Italy about the time of its first appearance. Manardi, a professor of the University of Ferrara, attributes it to "the impure commerce of a Valentian gentleman who was leprous with a prostitute." Gab. Fallopio, a Modenese physician, puts it down to the poisoning of the well-water by the Spaniards in the war of Naples, which water being drunk by the French gave rise to syphilis. Andrea Cesalpina, physician to Clement VIII., relates that the Spaniards in the same war, escaping from Somma, which was besieged, left behind them a great number of jars of Greek wine mixed with the blood of the sick of San Lazaro, which being discovered and drunk by the French produced syphilis in their army. Leonardo Fioravanti, a Bolognese physician, in his "Capricci Medicinali," asserts that in the year 1456 both the French army and that of Alfonso, king of Naples, being short of provisions were supplied by the sutlers with human flesh dressed in such a manner as to resemble that of the tunny fish, upon eating which they were afflicted with syphilis. Vatablo Peneda and other authors ascribe an even more ancient origin to the disease, for they assert that it is none other than that from which the patriarch Job suffered; indeed, so widely did this view gain credence that for a considerable period after its first appearance in Italy it was generally known in that country as "Job's evil," though in what manner it had been transmitted from the patriarch's time to the fifteenth century none of these ingenious authors attempt to show.

The first authentic account which we have of an undoubted outbreak of syphilis in Europe, during the year 1494, tallies exactly with the return of Christobal Colon from his first voyage to the Indies, which took place in March of the previous year. Moreover, Ruy Diaz de Isla, a physician of Seville, affirms that several of Colon's men suffered on board ship from this disease, which they had contracted in Hispaniola, and that on their landing in Barcelona, where the court was then held, they spread the contagion, so that this city was the first affected, the epidemic becoming so serious that "prayers, fastings, and almsgivings were appointed to appease the anger of God." Oviedo affirms that the syphilis which was prevalent amongst the soldiers

of the great Captain Gonzale de Cordova, in his campaign against Louis XII., had been introduced by some of the members of Colon's company who formed part of the army, the disease having been first introduced by D. P. Margarit, one of the Spaniards who returned with Colon in 1496 from his second voyage, and by him communicated to some prostitutes, through whom it rapidly spread.

Astruc, in his "De Morbis Venereis," vol. ii., Venice edition, upholds the American origin of syphilis. Speaking of the island of Hispaniola, he says: "Multis ergo et gravissimis morbis indigenae insulae Haiti affici olim debuerunt, ubi nemo menstruatibus mulieribus se continebat; ubi viri libidine impotentes in venerem obvium belluarum ritu agebantur; ubi mulieres impudentissimae erant, viros promiscue admittebant ut testatur Consalvus de Oviedo, Hist. Ind., lib. v., cap. 3, immo eosdem et plures impudentius provocabant menstruationis tempore cum tunc incalcescente utero libidine magis in-anerent pecudum more. Quid igitur mirum, varia, heterogenea, acria multorum virorum semina una confusa, cum acerrimo et virulento menstruo sanguine mixta intra uterum aestuantem et olidum spurcissimarum mulierum coarcta, mora, heterogenitate, calore loci brevi computruisse, ac prima morbi veneri semina constituisse, quae in alios, si qui forte continentiores erant, dimanavere." Astruc, though an authority upon the place of origin of the disease, can hardly be looked upon as such in regard to its causation and pathology. He considers the venereal poison to be due "to the wheyish part of the lymph assuming a singular thickness, and acrimony, due to an acid salt, corrosive and of a fixed nature."

Nicholas Monardes, a physician of Seville and a contemporary of Diaz, says: "During the year 1493, in the war of Naples, between the Catholic and the French kings, Columbus arrived after his first discovery of the island of Hispaniola, and brought with him from that island a multitude of Indians, men and women, whom he carried to Naples, where the Catholic king then was, after the war was over. And as there was peace between the two kings and the armies communicated together, when Columbus came there with his Indian men and women the Spaniards began to have commerce with the Indian women, and the Indians with the Spanish women, and in that manner the Indian men and women infected the Spanish army, the Italians, and the Germans."

Las Casas, "the Bishop of the Indians," who, though a Spaniard, was violently prejudiced in favour of the Indians, admits that they readily acknowledged the presence of syphilis amongst them long before the coming of Europeans. Dr. Gustavus Beühl of Cincinnati, Ohio, who has made considerable research into the subject, shows from the writings of the early Spanish historians that the disease was not only well known amongst the native tribes, but that amongst the Mexicans its treatment was far better understood than it was in Europe for many years after its first introduction, and that those who died from this disease were not (as was customary) cremated, a fact the importance of which will appear later. The Maya language, which is almost universally spoken by the Indians of Yucatan, Honduras, and parts of Guatemala, and Mexico, has a special name for syphilis, and not one borrowed from the Spanish, or coined either from a fancied resemblance to the sound of the Spanish name or some prominent characteristic of the thing named, as is the case with most of the numberless new objects introduced at the conquest. Dr. Hyde, in an article entitled, "Pre-Columbian Syphilis in America," published in the *International Journal of Medical Sciences* for August, 1891, strongly upholds the pre-Columbian existence of syphilis amongst the American aborigines. In this article are described and figured bones taken from ancient Indian sepulchres, many of which exhibit undoubted syphilitic lesions. Magellan asserts that it was a common disease amongst the inhabitants of Timor, an island in the Moluccan Archipelago, at the time of his visit. Clavigero, in his "History of Mexico," vol. ii., Dissertation 9, attempts to prove that the disease did not originate, and could not possibly have originated, in America, but his chief reason for upholding this view appears to be that his *bête noire*, M. de Paw, holds a contrary one. He affirms in support of his opinion that the disease, being a newly-introduced one amongst the aborigines of America, was on that account far milder and less malignant than amongst Europeans, but we now know that, on the contrary, all diseases newly introduced from Europe to America, such as small-pox, measles, &c., have proved

terribly fatal to the aborigines who almost invariably suffer from a highly malignant form rarely seen in the Old World where through centuries of transmission they have become more and more modified in form and less malignant. The fact, therefore, that the Indians were and are less liable to the disease than Europeans and suffered from a milder form would rather go to prove that the disease had been common amongst them for centuries.

The mound to which I alluded at the commencement of these notes was situated in the northern district of the Colony of British Honduras, near the village of San Andres. It was nearly circular at the base, conical in shape, 18 feet high by about 90 feet in circumference, and built throughout of large blocks of limestone, the interstices between which were filled in with limestone dust and earth, forming together a sort of mortar which made the whole structure nearly as solid as masonry. An excavation was commenced near the centre of the mound and at a depth of about two feet below the surface a large circular disc of roughly-hewn limestone was brought to light. On lifting this it was found to cover a well-like cavity three feet in diameter by about five feet deep. At the bottom of the hole lay a roughly made, circular earthenware pot, 18 inches in diameter, covered by a lid. Within this pot, together with a number of other objects, were found two rudely-fashioned earthenware figures, one of which is shown in the illustration. A third figure was also

Clay figures found in a Maya tomb.

found, which was precisely similar in every respect to those depicted; this has been purchased by the British Museum, where it may now be seen. Each of these little clay figures is about four and a half inches in height, and represents an individual, who, from his head-dress (not unlike our bishop's mitre) is probably a Maya priest seated on a low four-legged stool. The genital organs are in all three cases out of all proportion to the magnitude of the figures, probably with the idea of drawing special attention to them. The penis, which is represented as being nearly as large as the leg below the knee, is grasped by the glans, in one case with the left and in the other with the right hand, whilst the other hand holds a long pointed implement, with which it is evident that some operation is either about to be, or has been, performed on that organ, probably the latter, as upon the upper surface of the glans, which is enormously enlarged and flattened from above downwards, several scarifications are seen. That these earthenware figures were manufactured by the Mayas before the coming of Europeans is abundantly clear from the fact that they wear the huge circular earrings, and one of them the circular lip ornaments of ancient times; and also, as before stated, that they wear the priestly head-dress of the Mayas. Moreover, with them were found several clay figures of

alligators, which amongst the Mexicans were symbolical of Death the devourer of all, and in this connexion were frequently buried with the dead in pre-Christian days. The figures when first discovered were exceedingly brittle and it was found impossible to remove them from the pot without breakage, as they had probably been only sun-dried; after exposure to the air and sun, however, for a few days they gradually hardened. All the clay objects found in this pot were painted in various devices with bright colours, chiefly red, blue, yellow, and black; the colours had, however, from centuries of exposure to the damp become considerably dulled and defaced. The only unpainted object of clay found in the jar was a natural-sized model of the human penis in a state of semi-erection. This is an exceedingly accurate model and differs from all the other clay objects in that it has been fired instead of merely sun-dried, and is on that account much harder. Upon the upper surface of the glans penis are three longitudinal incisions extending almost from base to apex and evidently made with a sharp-pointed implement whilst the clay was still soft. Together with these clay figures a number of perforated beads of jade and some dark red stone, all nicely polished, were found; also the tooth of a large alligator, perforated at its base, evidently for suspension with the beads. At a distance of about six feet to the north of the centre of the mound and at a depth of three feet below the surface was discovered a small square stone cyst or chamber, measuring 18 inches in every direction, and built of roughly squared blocks of limestone; within this were found most of the bones of a male of medium height and of fair muscular development. The bones were exceedingly friable, many of them, indeed, having disappeared entirely; they showed no signs of partial cremation, and with the exception of the tibiae were in no way abnormal. The upper articular surface of the right tibia had disappeared. The shaft instead of being triangular was rounded in section, the prominent angles at the front and sides being obliterated; it was slightly bowed, with the convexity anteriorly, and was a good deal enlarged, especially in its upper two-thirds, which were composed chiefly of friable, spongy, cancellous tissue which rendered the bone much lighter than it appeared. The surface was exceedingly rough, especially in the upper part of the bone, being covered with a number of small nodular outgrowths, between which were small pits or depressions. The bone was not examined microscopically. Of the left tibia only small fragments remained, but as far as could be judged from these a change somewhat similar to that undergone by the right bone had also taken place here, though not to such a marked extent. It was impossible to identify the fibulae, as only small portions of bone corresponding to them in circumference were to be found, the articular extremities of which were absent. I have opened nearly 100 ancient mounds in Central America, a large number of which have proved, from the presence of bones within them, to have been at least partially sepulchral in origin, but this is the one solitary instance in which the interment took place within a stone chamber without any previous attempt at cremation. The most usual method of disposing of the dead appears to have been, first, to cremate, or partially to cremate, the body (usually the latter), and then to collect the ashes and fragments of bone in an earthen jar, which was buried in a mound together with a number of the possessions of the deceased, such as spear, arrow, and axe heads, obsidian knives, skin rubbers, beads, and other ornaments, &c., and in the case of children, toys of various kinds. Occasionally, though very rarely, bones are found in an urn which show no traces of cremation, in which case the interment must have been secondary, the bones being collected from the first place of burial and re-interred within the mound in which they were found. The reason for this was probably that the individual either died or was slain in battle at a distance from his home, and it was either impossible or inconvenient to remove the corpse at the time. In the present instance it is evident that the bones had been collected after the flesh had either been removed or decayed away from them, as it would have been impossible to bury the corpse of a full-grown man within the small cyst in which the bones were found.

The foregoing facts taken together form, I think, a chain of evidence in proof of the individual who was buried in this mound having died from syphilis which is almost irresistible.

To recapitulate: 1. The clay figures, indicating that the persons whom they were meant to represent suffered from

some disease of the penis, confined apparently to the glans, a supposition which the life-sized penis tends to confirm. It is, of course, conceivable that as these figures were dressed as priests they may have been performing some ritual act of self-mutilation, a common occurrence, as we know from contemporary writers, amongst the Maya priests, but these acts were, as far as is known, confined to cutting and slashing the limbs and drawing twigs and small ropes interwoven with thorns, through a recently-made slit in the tongue, no author having mentioned mutilation of the penis. 2. The condition of the tibiae, which may, of course, have been due to caries or other morbid changes unconnected with syphilis; but when we remember that both bones were affected, that the tibiae are favourite sites for syphilitic morbid changes, and that the owner had evidently been afflicted with some disease of the glans penis, from which he presumably died, the evidence in favour of syphilis is overwhelming. 3. The peculiar and unique method of burial. We know from the accounts handed down by Sahagun, Torquemada, and other Spanish historians that amongst the aboriginal tribes persons who died from syphilis were not cremated (as was customary), but had a special mode of burial accorded them, and here, I think, we have it before us.

Corozal, British Honduras.

## A REMARKABLE CASE OF A FOREIGN BODY IMPACTED IN THE RECTUM.

WITH REMARKS.

By A. MARMADUKE SHEILD, M.B. CANTAB.,  
F.R.C.S. ENG.,

SURGEON TO ST. GEORGE'S HOSPITAL.

A THIN, spare, grey-haired man, aged 60 years, was admitted into St. George's Hospital in July, 1901. Four days prior to admission he had forced a gallipot up the rectum. He had passed some loose evacuations since and there was no great pain or difficulty in micturition. Strenuous attempts had been made by the patient to remove the pot with the fire-irons and some pieces had been broken off, with the result that large, irregular, sharp, jagged projections of earthenware presented downwards towards the anus, burying themselves in mucous membrane and seriously increasing the difficulty of extraction.

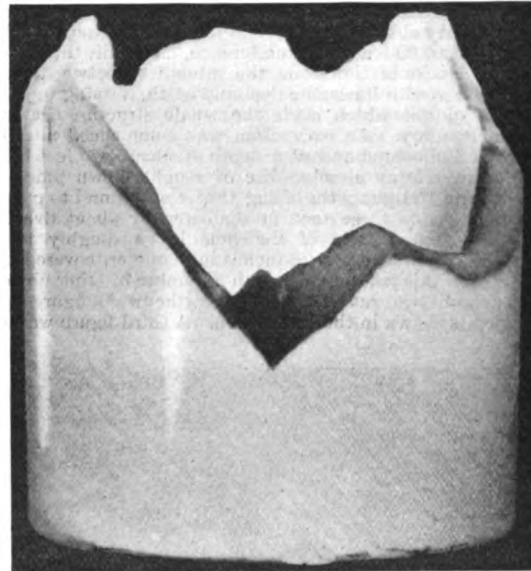

An anæsthetic was administered and the broken ends of the gallipot could just be felt by the index finger, but they were embedded in swollen and prolapsed mucous membrane. Knowing the perilous nature of these cases and the extreme difficulty experienced by others in similar circumstances I made no serious attempt at extraction until I had divided the bowel posteriorly. The incision was very free, down to the coccyx behind, and the bistoury was entered above, close to the foreign body. A short-bladed pair of midwifery forceps were next employed and I endeavoured as far as possible to engage the most dangerous jagged projections in the blades of the forceps. With careful traction and "swaying" movements the mass passed into the large wound whence it was easily extracted. Its extraordinary size and form are well seen in the accompanying illustration from a photograph kindly taken by my late dresser Mr. J. W. Seccombe. I united the great posterior wound with deep sutures, but these had to be removed soon, for the parts became very septic. The wound was lightly plugged as in a deep fistula operation and a warm boric hip-bath was constantly employed. Thanks to the care taken of the case by the nurses and Mr. W. F. Fedden (the house surgeon) the patient made a good recovery, which was interrupted only by a slight pleuritic attack. The wound is now not quite healed, but he is recovering power over his motions gradually.

No motive could be assigned for this rash and foolish act. The patient's wife stated that he was a morose man, unsuccessful in life, but that she had never noticed symptoms of insanity. She believed that he had occasionally inserted potatoes into the bowel and she had taxed him with this act.

Perusal of the cases presently to be related will show that these curious accidents are by no means devoid of great peril. The risk of lacerating the mucous membrane is very great and the impaction seems peculiarly tight. Indeed, in

the St. Bartholomew's Hospital case spoken of below the abdomen had to be opened and pressure brought to bear upon the foreign body from above before extraction could be effected by traction.

The rarity of foreign bodies being introduced in this manner may be gauged from the few instances which I am able to relate in this communication. A case was related in 1896 by Mr. J. Good,<sup>1</sup> then of Leominster, which occurred in a man,

Jam pot, exact size, extracted from the rectum.

aged 74 years, who had suffered from diarrhoea with passage of blood and mucus. Examination detected a foreign body and then the patient confessed to having introduced a "Worcester sauce bottle." Mr. Good removed the bottle by passing a gum catheter round it and making traction. The long neck of the bottle appeared to be tilted forward and had caused retention of urine, which was relieved by its removal. I have addressed queries to the custodians of all the principal hospital museums in Great Britain and Ireland with little result. The great collection in Edinburgh, for instance, contains only specimens which have descended into the lower bowel from above. Thus Series 26 contains one instance of intestinal concretions, one of a large gall-stone, two of doubtful substances, and one of a nail which had been swallowed. The Hunterian Museum in London contains no such specimens, though it exhibits such curiosities as a swallowed table-spoon which reached the cæcum and an egg-cup impacted in the ileum. In conversation, however, I have heard of cases similar to the one I relate which have never been reported, and the treatment is so difficult and dangerous that all such accidents, however rare, are worthy of being related.

Mr. W. E. S. Burnett of Mottram furnished to Mr. Harrison Cripps the particulars of an instance of impacted jam-pot, and I suspect that this is the case referred to by the other authors. Here a tall and robust man of temperate habits and sound mind forced a jam-pot up his anus. Afterwards finding that it obstructed his motions he knocked out the bottom with a poker. The prolapsed intestine had passed through the opening in the bottom of the pot, which was uppermost, and was swollen and pulpy. In one and a half hours Mr. Burnett succeeded in removing the pot by crushing it with a craniotomy forceps and syringing. The patient would not take an anæsthetic.<sup>2</sup>

The majority of these curious cases, however, seem to have originated in a desire to treat some rectal complaint, imaginary or real, as chronic constipation or worms. Authors speak of the impaction of an eau de Cologne bottle and of a jam-pot two and three-quarters of an inch in diameter which remained in the rectum for six days.<sup>3</sup> This last

<sup>1</sup> Brit. Med. Jour., Nov. 7th, 1896, p. 1427.

<sup>2</sup> Cripps: Diseases of the Rectum, p. 284.

<sup>3</sup> Cooper and Edwards: Diseases of the Rectum, p. 304.

instance is probably the same as that quoted by Mr. Cripps. One of the earliest recorded cases in this country is related by a Mr. Thomas, who in 1812 introduced his whole hand into the rectum and removed a piece of cane nine inches long. The patient had used this habitually for the relief of constipation.<sup>4</sup> Thus this surgeon may be looked upon as the pioneer of rectal exploration by means of the hand.

Mr. Laurence Cripps has kindly copied out for me the following interesting accounts of the specimens in the Museum of St. Bartholomew's Hospital:—

"3391 W., St. Bartholomew's Hospital Museum.—A white glazed porcelain jar, measuring three and a half inches in length and nearly two inches in diameter, which was removed by operation from the rectum. The jar is similar to those used for the preservation of Liebig's extract of beef. The patient was a man, aged 35 years, who placed a small potato in the orifice of the jar and then sat on it to allay, as he said, intense itching at the anus. The jar slipped into the rectum. He came to the hospital and attempts were made with midwifery and other forceps for over two hours under an anæsthetic to remove the jar, but unsuccessfully. The next day he was again placed under an anæsthetic and the sphincter ani was divided back to, and on either side of, the coccyx. It was not, however, until the abdomen had been opened and the jar (with the potato still impacted) had been pressed down from within by the hand of an assistant that it could be extracted. So much injury had occurred to the rectum and the surrounding tissues that peritonitis set in and proved fatal."

"3391 G., St. Bartholomew's Hospital Museum.—Two masses of silver ore removed from the rectum of men working in the silver mines of Chili. The larger mass weighs 30 ounces and measures five and a half inches in its longest diameter and eight and a half inches in circumference; the smaller one weighs eight ounces. A gentleman living in Chili who sent the specimens to England writes: 'In the silver mines here the men on coming out of the mine are stripped naked and well searched. Among other habits some of them accustom themselves to pushing pieces of ore into the rectum, leaving a short piece of string to pull it out by, and some of these miners are by this means able to steal during the year a large amount of silver ore. I was present the other day when the men were leaving the mine and saw the searching. The two specimens I send were taken from the rectum of two of the miners. I have seen even larger pieces removed than these.'" The enormous size of the silver ore would indicate that the thief had long used his rectum for purposes of concealment.

In reference to this latter case it may be remarked that the Kaffirs in the Kimberley Mines secrete diamonds in the same way. A well-known resident in South Africa informed me that it was customary to give the natives powerful purgatives before they leave the "compound" after their term of work is concluded. By this means diamonds of value are not infrequently recovered.

The only other case of the kind which, so far as I know, has occurred at St. George's Hospital is as follows. It well illustrates the inevitable danger of laceration. In March, 1890, a man, aged 45 years, was admitted into St. George's Hospital with a foreign body in the rectum. He had long suffered from prolapse and to relieve this he forced up the bowel a glass pomade-pot. He was admitted very ill and the pot could just be felt with the index finger. Prolonged attempts were made to remove it, but without avail, by means of hooks. The sphincter was finally divided and the pot was extracted with a midwifery forceps. The patient died from peritonitis. A small laceration was found anteriorly about three inches up the bowel which opened the peritoneum. This had obviously been made by one of the hooks unavailingly used in extraction.

Pages might be written regarding foreign substances lodging in the rectum which have been swallowed and have come down from above. Intestinal concretions, fish or other bones, tooth-plates, coins, pins, and needles are familiar examples. Some of these have been swallowed by accident, others by design, by jugglers, children, hysterical persons, or lunatics. It is a cardinal rule that when a person of unsound intellect exhibits symptoms of rectal irritation, as the passage of blood and mucus with "spurious" diarrhoea, to suspect that a foreign body may have been introduced, by the mouth or otherwise. Probably the experience of these engaged in lunacy practice could

supplement this. Again, a class of foreign bodies in the rectum may be found which have been introduced by pure accident. Such may result from breaking an enema apparatus, or a fall on the buttocks on broken wood or glass or china. With all such cases as these, which are in the knowledge of all practitioners of experience, this short paper does not profess to deal. Should any surgeon meet with one of these curious and embarrassing accidents, the experience of this paper will not be devoid of utility to him. The division of the structures posteriorly seems an essential preliminary to any attempts at extraction. I should not hesitate to remove part of the osseous structures if needful. Short midwifery forceps are probably safer instruments for extraction than any hooks or weapons which might inflict laceration.

## A CASE OF LAPAROTOMY

FOR MULTIPLE SEPTIC ABSCESSSES AND INTESTINAL ADHESIONS POSSIBLY DUE TO SALPINGITIS, CAUSING OBSTRUCTION, FOLLOWED BY A SECOND OPERATION NINE DAYS LATER FOR ACUTE OBSTRUCTION DUE TO A BAND AND VOLVULUS; RECOVERY.

By A. ERNEST MAYLARD, M.B., B.S. LOND.,  
SURGEON TO THE VICTORIA INFIRMARY, GLASGOW.

I AM tempted to record this case not only because of the triple cause which had led to acute intestinal obstruction but also as an illustration of what surgery can do, or better, perhaps, what nature can endure and repair. As an example of intra-abdominal tolerance of surgical manipulations it exceeds anything that has hitherto come within my experience, and shows that nature sometimes prefers even the most radical surgical intervention to the baneful influences of certain pathological conditions.

The case was that of a young woman, aged 17 years, whom I was asked to see in consultation with Dr. Archibald Brown of Mount Florida on April 19th, 1901. The symptoms at this date were not particularly clear, although sufficiently grave. They suggested subacute obstruction dependent upon some inflammatory condition, although upon what the latter depended it was impossible to say. As it was considered that some slight improvement had taken place since the onset of the illness a few days previously, and that, according to the parents' statement, their daughter had recovered from a somewhat similar, though not so severe, attack before, merely palliative measures were suggested. I was not asked to see the patient again until May 3rd, that is to say, a fortnight after my first visit, when I was informed that while improvement had seemed to take place for a time she had now become very ill again. When seen on this second visit she was extremely ill with evident symptoms of acute intestinal obstruction and a temperature of 102° F. I had her removed to a private room in the Victoria Infirmary as soon as possible and made all arrangements for the performance of the operation on her arrival. As pain had been mostly felt in the left iliac region and there were both tenderness and resistance over the same area, I made my incision through the parietes at this part. On opening the peritoneal cavity a stream of fetid pus escaped. The intestines were glued together, and as they were detached localised collections of extremely offensive pus were liberated. The left appendages were found in one of these pockets, the ovary being cystic and the tube thickened and distended. In detaching one portion of bowel the serous coat was torn; this was carefully stitched with a continuous Lembert suture. All pus and inflammatory exudate were removed as exposed by means of small swabs of gauze. As the patient's condition became alarming no further attempt was made to remove the appendages, but the various septic areas were plugged with iodoform gauze and the parietal wound was rapidly closed as much as the "stuffing" would allow.

Although greatly collapsed after the operation the patient soon rallied and in the evening both flatus and fæces were passed per rectum. For eight days progress continued uninterrupted, except that a bad bed sore formed over the sacrum, the result of the extreme degree of emaciation to which she had been reduced. On May 12th, nine days after the

operation, I found her on my morning visit suffering from evident symptoms of acute intestinal obstruction and concluded the cause to be some kinking or binding down of the bowel, the result of the adhesions about the seat of the original operation. The patient was again removed to the operating-theatre and an incision was made through the parietes in the median line below the umbilicus. As my object was not only to liberate the supposed involved loops of intestine but to remove the left appendages, I preferred to do this through a fresh incision in the median line rather than to re-open the existing septic channel. My first encounter was with another localised foetid abscess which was encircled and retained by loops of matted intestine; this, as in the previous one, was swabbed out. At the same time every precaution was taken to prevent any septic infection of the upper part of the abdominal cavity. The matted intestines were again disengaged and withdrawn from the abdomen so as to ensure of no involved loop escaping observation. Search was then made for the left ovary and tube, but these were found so inseparably matted to the anterior wall of the pelvis, and free from any neighbouring septic material, that it was decided not to prolong the operation by any attempt at their removal. When it was supposed that the operation was completed so far as the intra-abdominal part was concerned, it was accidentally discovered that a distended and congested loop of small intestine presented at the upper part of the parietal wound. The parietal incision was extended upwards sufficiently to expose the bowel above, when it was found that a tense fibrous band extended transversely across the gut, completely occluding it. The band was divided but the bowel failed to empty itself onwards; hence an incision was made into it and its contents were allowed to escape, or rather were made to escape, by passing the distended gut between the fingers. Another difficulty now presented itself. It was found impossible to empty even by this manipulative process a long coil of small intestine lying higher up in the abdomen. On searching for the reason it was soon found that this loop of intestine had formed a complete twist upon its mesentery. When untwisted the remaining contents of the distended gut were easily squeezed out through the enterotomy wound. The patient by this time was almost *in extremis*. It took, however, but a few minutes longer to close the enterotomy wound and to return the collapsed bowel. During the intestinal manipulation I came upon the appendix which while containing a faecal concretion was entirely free from any inflammatory complications. It was, however, accidentally removed, for in our excusable hurry, it suddenly gave way near its attachment to the caecum, while being held up. Time did not permit of our performing the toilet connected with an appendicectomy, so reliance was had upon the stuffing which was freely employed here as in other septic and doubtful areas of the abdomen. The patient was got back to bed where she lay for some time in a profoundly collapsed condition. With, however, the unremitting and constant attention of my assistants, Dr. David Russell and Dr. John Duncan, and my nurses, the patient not only rallied but made an almost uninterrupted recovery. I say "almost" because for some time there was a faecal fistula at the lower part of the median incision. I believe this was the result of the unintentional and uncompleted appendicectomy. It, however, eventually closed.

In reviewing the case from its pathological aspects I must own to difficulties in rightly interpreting the cause, or causes, of what I found. I have ventured to suggest salpingitis as the origin of the mischief first dealt with and yet there was nothing in the history of the case to allow of the slightest suspicion as regards a vaginal or uterine discharge of any kind. The tube was certainly thickened and apparently distended; but might not this have been the result of external inflammatory influences? Is it possible that a tuberculous lesion could have explained all the conditions found? The intestine showed no evidences whatever of ulceration so far as could be judged from external appearances. But I have no intention of pursuing further this aspect of the question. I have recorded the case merely as one which seemed to me to possess, from a practical surgical aspect, several points of interest. Not the least of these were those connected with the natural power of the peritoneum to resist the severe and extensive mechanical interference when it failed, or was failing, to combat successfully grave and fatal pathological processes.

Glasgow

## MUCIN IN DESICCATION, IRRITATION, AND ULCERATION OF MUOUS MEMBRANES.

By W. STUART-LOW, F.R.C.S. ENG..

ASSISTANT REGISTRAR CENTRAL THROAT AND EAR HOSPITAL.

LAST year I published a paper dealing with the use of mucin in gastric ulcer, but then I could only speak on the subject tentatively, because I had employed mucin only in a limited number of cases, although very successfully. During the last 12 months, however, the more extensive use of this natural remedy has more than ever convinced me, as also others who have made application of it, that in suitable cases it is a most valuable therapeutic agent and that it will afford relief and sometimes cure when all other treatments fail. To better understand the premises on which the arguments in favour of the use of mucin are based it is necessary to refer to certain anatomical and physiological points. The interior of the nose and that of its accessory cavities are lined by mucous membrane and the provision for the secretion of mucus in the inner lining is very complete and extensive. In the olfactory region—all above the middle of the middle turbinated bone—there are comparatively few muciparous cells or glands. In the regio respiratoria—all below the middle of the middle turbinated bone—the contrast with this anatomical condition is very marked and the special provision that is here made for the secretion of mucus shows how important the presence of this secretion is and what a large quantity must constantly be poured out even in the normal nose. In the sphenoidal sinus there are about 20 muciparous glands. The lining membrane of the accessory cavities is a thin one with a ciliated surface, a thin basement membrane, and sub-mucous tissue, and the glands are mostly aquiparous. There are some mixed glands in the antrum maxillare, but in the ethmoidal cells and frontal sinuses the secretion is watery. The fact that the lower or respiratory tract is much the wider when compared with the upper or olfactory tract which is narrow and slit-like, thus affording a vastly larger surface for secretion, is also noteworthy. The most closely packed gland surface in the body is the stomach surface, where there are the open mouths of glands to the number of 100 to the square centimetre; on the nasal septum gland openings are similarly exceedingly abundant. The gland openings, mostly muciparous, are found numbering as many as 70 to the square centimetre and on the inferior turbinated bones also these glands are very numerous, being only slightly less thickly placed than on the septum. This is also the condition conspicuously seen on the mucous lining of the lower half of the middle turbinated bones and also in the posterior part of the outer wall of the nasal cavity.

The next point of importance, anatomically, as defining the direction of the flow and ultimate destiny of all the mucous discharges in the normal nose, is the slanting position of the three turbinated bones and therefore of the three meatuses. These three bones and cavities all lie obliquely from before backwards and above downwards, and even the floor of the nose in the erect position of the head is inclined towards the pharynx although it is the least oblique of the meatal floors. The result of this structural arrangement is that the secretions slide backwards into the pharynx preparatory to passage down the oesophagus into the stomach. The sphenoidal sinus secretion in dependent positions of the head must also pass into the pharynx from the roof. The more watery discharges from the upper regions and accessory cavities will tend to flush mildly the more viscid secretions lower down on into the pharynx. The only secretion passing into the nose that might have a chance of escaping passage back into the pharynx is that from the lacrymal apparatus which is more or less constantly flowing from the anterior position at which it enters; but the oblique inclination backwards of the nasal duct, the valvular fold at its abutting point, and the curved formation of the anterior part of the inferior turbinated bone, all tend to direct the flow pharynx-wards.

In the pharynx there are small groups of muciparous glands on the lateral and posterior walls in its upper part;

there are also a considerable number on the pharyngeal surface of the uvula; but below the upper level of the mouth, where the epithelium changes its character from ciliated to stratified, there are very few. There are also very few mucous glands in the œsophagus until nearing the cardiac orifice, where there are a great many rather large ones, intended doubtless to supply mucus to afford protection against acid regurgitation from the stomach. This paucity of mucous glands below the middle of the pharynx is explained by the fact that the dependent secretions from above are meant to be swallowed and thus to lubricate and protect the lower half of the pharynx and the œsophagus. Besides the special glandular arrangement for the mucous secretion there is a large quantity supplied also from muciparous cells scattered throughout the nasal and upper pharyngeal regions, wherever the epithelium is of the columnar type, many of which cells exhibit the goblet condition. In the mouth most of the mucus is supplied by the sublingual glands. The sub-maxillary being a mixed gland supplies a smaller quantity. There are also groups of special mucous glands—viz., the buccal, labial, molar, and lingual. The use of the oral mucus is doubtless that of facilitating the preparation of the food for deglutition and the maintenance of the cavity in a fit and moist condition.

That there is a considerable secretion of mucus in the nasal cavity and upper pharynx the study of their anatomy leaves no doubt, and that this secretion is far more than is required for the purposes of lubrication or for its special function of keeping up the moisture of these parts by virtue of its hygroscopic properties cannot be questioned. I maintain that this abundant mucus is swallowed, is normally intended to be so swallowed, and that in this manner not only is the œsophagus continually protected and lubricated, but that the ultimate function of this deglutated nasal mucus is to assist in protecting the stomach, more especially the pyloric portion (to which it immediately gravitates), against attrition by lumpy food and irritation by the acid gastric juice. It also helps to act as a natural laxative.

The nearly vertical position of the stomach, especially in its cardiac part, necessitates the gravitation of the swallowed mucus to the pyloric end where it is most required on account of great mechanical strain thrown on this part and the irritation caused by the acid juices. The cardiac portion has only feeble contractile power compared with the part beyond the so-called prepyloric sphincter, in which the muscular power is very great indeed. This differentiation between the two parts of the stomach, both anatomical and functional, is not sufficiently taken into account when studying their respective liability to disease, more particularly irritation and ulceration. Immediately on passing through the cardiac opening the epithelium changes its character again from stratified to deep columnar, and what is a very striking fact will be noticed—that every cell on the gastric surface is an active mucous gland pouring out its secretion over the surface, thus saving the sensitive walls from irritation and digestion by the gastric juice. These surface cells also line the mouths and necks of the gastric glands.

The functional differences between the two parts of the stomach is carried out not only in their musculature but in the nature of the glandular secretion, the cardiac glands giving out acid and pepsin and the pyloric ones pepsin alone. The mucous membrane at the pyloric part is much thicker than at the cardiac part, and the surface cells extend a much greater way into the wider openings of the glands than at the cardiac end, the mouths of the glands being always plugged with mucus. There is also another histological distinction at the pyloric part, in that there is a special readiness on the part of the new cells, intercalated between the deeper parts of the surface cells, to take the place of the old ones as they become rubbed off or worn out—young cells being found growing rapidly in the deeper layers. This is always an indication of special functional activity—in this instance of the goblet cells on the surface being quickly replaced as they are so soon worn out in mucus formation, again emphasising the need of much mucus at this part.

In the small intestine, with a capacity three times that of the stomach and four times that of the large intestine, the surface epithelium has the distinctive features of a striated border, stamping this as the chief absorptive part of the intestinal tract, far exceeding in this capacity both the stomach and the large intestine. The other marked feature in the lining membrane of the small intestine is the

sparseness with which mucous cells are found. There are only a few goblet cells found scattered over the villi, a few in the glands of Lieberkühn, these Lieberkühn glands being interspersed like test-tubes in a stand between the villi; this is in great contrast with the large number of goblet cells seen in the Lieberkühn glands of the large intestine, where as many as 40 are commonly found in one gland. The mucus in this part of the canal—the small intestine—is an imported supply. From the stomach much is propelled onwards with the gushes of the chyme—from the pancreas in its very viscid secretions, and from the liver with its specially large supply in the bile, derived from tarrying in the gall-bladder and passage down the bile-ducts. The amount of mucus discharged into the small bowel, therefore, is very large—larger than in any other part of the bowel—but this is almost entirely derived from surrounding organs. That this is so, and that here the digestive processes are still carried on very intensely and actively, are important factors in their bearing on its pathology. The only other point I would like to emphasise about the anatomy of the small intestine is that the solitary glands and Peyer's patches, which are so liable to become the seats of ulceration, have only a single layer of protecting epithelium over them and that they are more liable to friction and irritation since they bulge up the surface somewhat and thus project into the lumen of the canal.

In the large intestine very great provision for mucus supply is met with, vast numbers of goblet cells being placed over the surface and in the glands of Lieberkühn throughout this tube. For lubricating and protecting purposes this is very essential, as the contents now become solid in consistency. I would here only further remark that while this is so in the large intestine—the vestigial part of it—the appendix has very few Lieberkühn glands and these are almost destitute of goblet cells. Mucin is the substance that gives the sliminess to mucus. It is found in many situations both in the cells of mucous glands and in goblet cells. It is also the chief constituent of the cementing material between cells—tissue mucin. There are probably several mucins. They are of a colloid nature, viscous, soluble in alkalies, but precipitable from such solutions by acetic acid. On boiling with dilute mineral acids they yield a substance which reduces Fehling's solution. Mucin is also found abundantly in such slimy animals as snails. It has been specially investigated in the jelly-like connective tissue of the vitreous humour, Wharton's jelly, and in tendons. By appropriate processes mucin is broken up into a carbohydrate called "animal gum" and a nucleo-proteid, and the unanimous opinion of physiologists is that mucin is not broken up in the digestive process, but that resisting them all it passes by the bowel unchanged. Some mucus may be broken up in the small intestine, however, and the great additional supply in the large intestine would support this supposition.

The solution of many of the pathological problems presented by the stomach which have perplexed the medical mind so long and so much is, I think, wrapped up in the solution of that other puzzling proposition. Why does the stomach not digest itself? which has hitherto never received a satisfactory answer from the physiologist. But what are gradual thinning of the surface epithelium of the stomach lining, multiple small erosions, either slight or to such a degree as to give rise to profuse hæmorrhage, ulcerations, few or many, superficial or deep, but the results of irritation first and then digestion and destruction by the potent acid gastric juice? This much is mostly agreed to be so by pathologists. But what preserves this superficial epithelium from solution if not the substance it secretes as mucinogen in the deeper parts of the cell body? This being rapidly changed into mucus which fills the outer part of the cell as a soft gluey plug resists gastric digestion and is poured, as a more or less thick layer, over the gastric surface. Any deficiency of this mucous coating must expose the deeper protoplasmic part of the cell-substance to the irritant and digestive action of the juice and also allow of its penetration into and between those cells, the prevention of which is very likely a further function of this mucus. A change has taken place in our views as to the functions of the stomach, inasmuch as it is not now considered to be a great absorbing organ, water even being mostly passed on to the small bowel, there to be rapidly taken up into the portal circulation. The principal action of the stomach consists in the completion of those processes of preparation for absorption begun in the mouth by the contents being churned and squeezed and triturated and by insatiation

and peptonisation being furthered, absorption being a subordinate function. That every cell on the stomach surface is a mucous gland is just what the organ's performances would lead us to anticipate—viz., absorptive duties much reduced in favour of mechanical work, when lubrication and protection from bruising by ill-masticated food and shielding from chemical irritation demand abundance of just such a substance as mucin. The stomach is said to resist self-digestion because its walls are living walls; and another reason assigned is that they are continuously being bathed in alkaline blood. But Bernard's experiments, in which he showed how the limb of a living frog even with its normal alkaline blood-supply was readily digested when projected through a gastric fistula into the stomach cavity of a dog, and that the ear of a rabbit when so introduced was digested (Pavy), clearly prove that living tissues are not thus resistant. It is singular that the epithelium of the pancreatic duct is not affected, although this juice is very active in an alkaline medium; but the explanation is probably the superabundance of viscid mucus in this secretion. Anything arresting the formation of mucus will lead to the digestion of the stomach walls. Thus the excised stomach of a recently-fed animal left in a warm chamber in a sufficient quantity of dilute hydrochloric acid will become completely digested (Waller's Physiology). An animal killed during digestion and examined a few hours later may be found with the stomach perforated by self-digestion and with more or less extensive destruction of the surrounding tissue (Waller).

It is interesting to notice in this relation that the margins of gastric fistulae in man are readily attacked by the gastric juice, as also are the margins of gastric ulcers. In persons dying after a full meal and the body being kept in a warm place not infrequently the posterior wall of the stomach is found digested and even the contents may escape. Fishes are frequently found after death with their stomachs partially destroyed. Ligation of the arteries of the stomach causes, according to Pavy, digestive softening of the gastric mucous membrane, and he thinks that this is brought about by the removal of the alkaline blood, but this has nothing to do with the explanation, for the frog's blood is also alkaline in Bernard's experiments just mentioned, and the cells that line the pancreatic ducts are preserved from the pancreatic juice which is intensely active in an alkaline medium. The true explanation is that ligation of the arteries arrests the secretion of mucus from the cells of the superficial epithelium of the stomach lining, while the already acid contents readily destroy the wall, and the great amount of mucus in the pancreatic duct shields it from the active secretion pouring over its surface. Stewart and Bernard are the only physiological authors who assign to mucus its proper place and role. In his "Manual of Physiology" Stewart says: "A certain amount of protection may be afforded to the walls of the stomach by the layer of mucus which covers the whole cavity, for mucin is not affected by peptic digestion, and a mucous secretion seems in some other cases to act as a protection to the walls of hollow viscera whose contents are such as would certainly be harmful to more delicate membranes—e.g., in the urinary bladder, large intestine, gall-bladders, &c." Bernard says: "The thick layer of mucus may also aid in protecting the stomach from the action of its own gastric juice."

After full consideration of the foregoing anatomical and physiological facts, and having noted that patients with irritable stomachs, painful digestion, and hæmatemesis (gastric erosions or gastric ulcers) suffered simultaneously in many instances from the accompanying ailments of either dry or atrophic rhinitis and pharyngitis, together with the prominence of the symptoms of a clear non-mucous hyperacid vomit, constant constipation of the bowels often with dry scybalous stools, amenorrhœa and chlorosis, I was induced to try the use of mucin in an endeavour to supply the obviously deficient mucus. In my position as assistant-registrar at the London Central Throat and Ear Hospital, examining a great many patients, I have been surprised to find how in almost all cases of dry nose and throat there is also complaint made of long-standing and intractable gastralgia and constipation of the bowels, and another fact that I have verified at the same large clinic is that the incidence of these affections as regards age and sex is much the same. It is remarkable that dry and atrophic rhinitis and pharyngitis and gastric erosions or gastric ulcer are most commonly seen in young females of the domestic servant or

indoor-labouring class between 17 and 30 years of age. There seems to be in such people and at such an age a special liability to desiccation of mucous membranes, beginning with lessened secretion and ending in more or less complete atrophy. This seems to be more often met with in the scrofulous, and is evidenced by dry nose and throat, these young women seldom using more than one handkerchief a week, while painful digestion, frequent vomiting after meals, constipation, amenorrhœa, and chlorosis are concomitant symptoms.

I will now give notes of a few of my cases treated with mucin.

CASE 1.—A woman residing in the country was sent to me that she might have special treatment, as all the ordinary remedies had proved futile. She had been under the care of Mr. Ray, late of Dulwich, on three occasions in the course of the five years for hæmatemesis, the last attack having been a very serious one, with much vomiting of blood and necessitating rest in bed and milk diet for one month. The diagnosis had been "gastric ulcer" and she had had painful digestion ever since the last illness. She was 34 years of age, very pale and emaciated, very weak and easily tired, and complained of want of strength, want of appetite, and pains after everything in the way of food—attacks of sickness and constipation. She had been very strictly dieted and practically starved, being afraid to eat. I found that the tongue was very clean and red and fissured and somewhat large and flabby-looking. The nose and throat were rather dry and the mucous membrane was thin and pale in appearance. She stated that she very seldom soiled a handkerchief. All her other organs were healthy. She had pain on pressure over the stomach and she stated that after taking food, even of a very light nature, she suffered great pain for some time and was often sick, the vomiting giving relief. I diagnosed the case as one of chronic gastric ulcer, the ulcer being most probably of considerable size and cicatrised over, with the edges liable to give way and to break down, thus accounting for the attacks of hæmorrhage. I prescribed tabloid mucin co. as prepared by Messrs. Burroughs, Wellcome, and Co., ordering three tabloid products just before food and three more just after food. The feeding was ordered to be carried out every three hours and to consist of soft food, especially Brand's essence of beef and thin cornflour made with milk. This was varied with calf's foot jelly, chicken and mutton jelly, and custards. There was no more vomiting and very soon the pain ceased, even after partaking of larger amounts of food at one time. In a week the patient was able to take a fairly good meal of chicken or fish, followed by custard or other light milk pudding. Her weight increased by eight pounds in six weeks. The number of tabloid products taken was gradually reduced from 24 per day to 16, which number was continued regularly for six weeks, and then as she was suffering no discomfort they were stopped as a regular thing and were taken only occasionally. With the help of a daily enema at first the bowels soon acted quite satisfactorily. When I last saw her she was quite well, although she had still to be careful of any indigestible article in her diet.

The following three cases were under the care of Dr. Hallam of Westminster and each made marked improvement under tabloid mucin co. These reports are from notes carefully kept by him.

CASE 2.—The patient was a girl, aged 18 years. She first sought medical attention on Jan. 19th, 1901, complaining of gastric pain after food and occasional vomiting. The ordinary medicines were prescribed, but at 2 A.M. on the following morning an urgent message was sent that she had vomited a chamberful of blood. Absolute rest was ordered for one week, and then she was allowed to get up, but she remained very weak, had no appetite, had much gastric pain, vomiting frequently after food, and was very constipated. She was now ordered two tabloid mucin co. products just before and two after each meal, the food to be taken every three hours. This treatment was kept up until the middle of April. Dr. Hallam says that "the pain and vomiting ceased very rapidly, and the bowels soon acted quite regularly," and that some time after he met the patient when she expressed herself as being in the best of health, having had no return of the symptoms, and stated that her bowels were now regular.

CASE 3.—The next case was that of a woman, 32 years of age, a thin, delicate-looking person, who complained of pain

soon after food, vomiting, and constipation. The tongue was clean and red. This woman had been quite incapacitated for two months and ordinary treatment had failed to relieve her. She was treated with tabloid mucin co., taking two tabloid products before and two after each meal. This was continued for a fortnight and the "bowels became regular and the pain and vomiting ceased and she was soon very greatly improved." This was evidently a case of irritable stomach or gastritis.

CASE 4.—The next case was that of a young lady who had had a great variety of treatment for acute gastric symptoms after partaking of food—gastric pain, sickness, nausea, and hæmatemesis. All the usual treatment had been gone through over a lengthened period but she had got no relief until put on tabloid mucin co. when she progressively improved.

Dr. H. Whittome of Camberwell used tabloid mucin co. in a case of "gastric ulcer" with good results. These are his notes: "The patient, a young unmarried woman, aged 28 years, came complaining of nausea, sickness, gastric pain aggravated by partaking of food, vomiting giving relief, and the passage of dark tarry stools. She had had only very temporary relief from soda, bismuth, hydrocyanic acid, and morphia and was therefore put on tabloid mucin co. These she took, two before and two after food, with cornflour, Brand's essence, and custards as diet every three hours; the pain and vomiting ceased and the bowels were moved twice daily. The tabloids were then reduced to half the number when improvement was still maintained, but the bowels only opened once daily. This patient took 250 tabloids in all. She kept for herself a very careful tabular record of the occurrence of pain, vomiting, colour of the motions, &c. A case of my own was very similar to this.

CASE 5.—A woman, aged 30 years, had long suffered from constipation and pain after food. She was a tall, thin, pale woman, with a clean red tongue and pale nasal mucous membrane and throat. I was asked to see her when she was suffering from a gastric attack with great pain, sickness, and vomiting tinged with blood, and the passage of tarry stools. I at first ordered absolute rest, ice to suck, a cotton-wool compress on the abdomen, Brand's essence of beef only for food, and tabloid mucin co., two tabloids every three hours. These had to be dissolved at first in a little warm lime water as she did not swallow them very well. She progressively improved and was convalescent in a week and with iron preparations and tabloid treatment occasionally has kept well ever since—now six months ago.

These are only a few cases that I have made a selection of, but they are typical of the others. I have had 30 instances in which mucin has had a most beneficial effect. Several patients have had to have a second course of tabloid treatment in from three to six months after the first, and some have had to have the treatment extended intermittently over a lengthened period, but in all my patients its success has been remarkably good.

The tabloid mucin co. consists of five grains each of mucin and sodium bicarbonate. I combine the mucin with sodium bicarbonate because mucin, as found in all secretions in the body, is always (as in the saliva) associated with an alkali and is sent into the stomach with alkalies, therefore, and is soluble in alkalies. If this tabloid compound is dissolved in a little water in a test-tube and kept at the temperature of the body a sticky, gluey adhesive liquid is formed. Alkalies, therefore, are essential to the full and proper action of mucin. I make use of mucin also for douching the dry nasal mucous membrane as well as for swabbing out the desiccated pharynx. For this purpose I have the same tabloid product combined with one grain of menthol. This tabloid product is dissolved by rubbing it up with an ounce of warm lime water and the solution is then used by means of a nose-boat or a nasal syringe to wash out the nose; this is equally effective half as strong and suits some sensitive people better.

Mucin is hygroscopic but its influence is not so violent or so irritating to mucous membranes as, for instance, glycerine is, because, according to a research I have had carried out at the Laboratory of Clinical Pathology, 62, Queen Anne-street, W., it has only about one-fifth of its absorbent power for water, 100 parts of mucin absorbing 3.8 parts of water in four hours, whereas 100 parts of glycerine absorbed 16.3 parts in the same time. Mucin is thus much more mild and soothing in its influence and therefore a more suitable moistening application to the nasal lining than glycerine, the effect of douching the nose with this preparation being agreeable, the surface keeping well moistened for the whole

day under ordinary circumstances. The douching may be repeated three times daily if desired, but in the majority of cases I find once daily quite enough to relieve the dryness and uncomfortable feeling.

How does mucin act? It acts by supplying what is deficient—viz., the protective, indifferent, non-peptonisable, and hygroscopic substance—mucus. By introduction into the gastric cavity first, before digestion begins, the sensitive ulcer or erosion or inflamed wall is covered over and shielded from irritation by the acid gastric juice, and by thus soothing the surface layer reflex secretion of the acid gastric juice is prevented, for it is believed that hypersecretion is thus reflexly brought about. It also doubtless acts by giving the epithelium resting time to recover itself and to revive and grow stronger, and thus to withstand the attacks of the acid contents—perhaps it allows the young epithelial cells time to replace their effete and broken up predecessors. Mucin, as the foregoing cases amply bear out, has undoubtedly a laxative action, thus acting much more valuably than subnitrate and subcarbonate of bismuth, both of which have hitherto been so much used under these pathological conditions, acting, of course, by being precipitated over the sensitive surface and forming a protective covering, but having the great disadvantage of causing constipation.

One of the leading clinical indications for the administration of tabloid mucin compound is the presence of a clean, red, angry, or dry tongue, frequently a clean, red, fissured tongue, indicating a deficiency of gastric protective coating, and this condition of tongue will often be found in association with a pale and thin, or a pale, thin, and desiccated, state of the mucous membrane of the nose and pharynx, or a semi-secretionless post-nasal and pharyngeal surface, as shown by hardly a handkerchief being used in a week and another almost invariable accompaniment—obstinately confined bowels. Now, just as in patients with deficient nasopharyngeal secretion streaks and tracks of old and functionless mucus may be seen on the nasal and pharyngeal walls, which must be washed away by alkaline douches just before using the mucin compound wash, so in some of these stomach cases, when, as in the dry nose and throat, there is really a greatly diminished production of mucus, the tongue will be found sometimes rather coated and dry than always red and clean or red, clean, and dry. But if in association with this there is pain after food and constipation of the bowels, such a tongue indicates not too much mucus in the stomach as in catarrhal states, but really shortage of mucus, and it will be necessary, in order to remove old gastric mucus and to prepare the way for mucin, to administer first a saline aperient. Such a saline aperient I find in the tabloid mag. sulph. co. or a saline aperient water may be prescribed, such as that of Carlsbad. I carefully avoid peptonised foods or preparations or peptonised milk in the treatment of such cases of gastric irritation and erosion and ulcer, because they are unphysiological. For the first half-hour, and most probably longer, the acid gastric juice ought to be immediately neutralised as it is secreted by union with alkaline salts introduced in the food, but chiefly by uniting with the proteids of the meal; this is essential so that the amylolytic process may proceed. It is of supreme importance that such neutralisation should take place in all irritable and ulcerated states of the stomach surface unless the exposed and hypersensitive parts are to be worried by the free acid, thus causing pain and inducing vomiting. Therefore, the administration of such prepared foods is to be avoided, and I find that as soon as a patient can retain such a proteid as essence of beef or fresh meat juice the pain becomes much less and I relegate the use of such prepared foods to cases of worn-out stomach in the aged.

Welbeck-street, W.

**MEDICAL SERVICE AT ST. LUKE'S CHURCH, LIVERPOOL.**—The Lord Bishop of Liverpool has signified his intention of preaching a sermon to the members of the medical profession at St. Luke's Church, Liverpool, on Sunday, Oct. 20th, at 3 p.m., being the nearest Sunday to St. Luke's Day. The President of the Liverpool Medical Institution has tested the feeling of members of the profession as to the desirability of their attending the service in academic robes with the result that a majority decided against the proposition. 24 gentlemen have already signified their intention of being present at the service and it is expected that a much larger number will attend. Should this new departure in Liverpool prove a success it is proposed to make the service an annual one.

## CANCER, ITS NATURE AND ITS TREATMENT.

By JOHN HOLDEN WEBB, M.R.C.S. ENG.,

L.R.C.P. LOND.,

FORMERLY HOUSE SURGEON TO ST. MARY'S AND LOCK HOSPITALS.

I HAVE just finished reading Professor J. G. Adami's address on the Causation of Cancerous and Malignant Growths, an excellent dissertation on the biology of the cell, but one that makes no effort to explain—which by its heading we might have expected—why tumours become malignant. This is a question which the professor of pathology himself asks and I should have been surprised if he could have answered it or even suggested an elucidation. It seems to me that the cause of malignancy can be fined down to one of two things: either the loss of, or a chemical change in, a secretion—the latter for choice—or else it is due to parasitic invasion. Nothing else seems to fit into the environments or clinical features of cancer, its variability, its persistence. Constant irritation, Cohnheim's suggestion, morbus miseræ, each have had their advocates and their day.

What are the arguments adduced in favour of the parasitic nature of malignancy—"infectivity"? In the absence of the production of a specific microbe the whole matter hangs on the question whether cancer may be conveyed or not. On the one hand, we have the fact that for generations surgeons, pathologists, and nurses have been in the habit of freely handling living and morbid specimens with complete impunity. Until recent years I do not think I ever remember anyone even suggesting that the disease was contagious, and instances are not uncommon where husbands have had regular connexion with their cancerous wives without any ill effect to themselves. In fact, it occasionally happens that the first indication of this dreadful malady is hæmorrhage and pain after coitus. I can recall to mind two instances at the present moment; one occurred 20 years ago and I often see the husband about in the streets. That is one side of the question. On the other side we learn that cancer is increasing in frequency. There is evidence that the malady is occasionally "localised" and that its recurrence is shown by statistical returns as intensified in certain places. These are houses built on alluvial soil, bends of rivers, and low-lying lands subjected to inundations. It is said that some buildings can even be designated as cancerous on account of the number of deaths that have taken place within their walls. Now, of course one cannot say that this is incorrect, that such is not the case; statements like those which appeared in the Cancer Number of the *Practitioner* are not to be denied by any direct evidence. Moreover, the statistics may be perfectly correct, but that does not show that the disease is microbic. For instance, just the same results might be obtained if the malady was due to such a local cause as a defect in the water-supply.

"Localisation"—the fact that in some parts of the world one valley will team with the diseases that result from the loss of the ductless gland secretion, while on the other side of the mountain the surroundings being, for all that is known to the contrary, exactly identical, gland trouble is scarcely to be found—is used as an argument in favour of infectivity. With respect to certain low-lying lands and alluvial deposits being favourable to the dissemination of cancer, many years ago, when I first arrived in Victoria, malignant diseases were frightfully prevalent all over the goldfields. Now, from Ballarat to Dunolly, which in one direction takes in nearly the whole of the gold area, there is not such a thing as a river, as the word is commonly understood. Of course, there are creeks which carry away the surface-water in winter, but alluvial valleys do not exist and, as is well known, we have no malaria. The whole country is a volcanic plateau, off which the rain courses almost as soon as it has fallen. Yet this was a veritable home for cancer, the formation of the country and its geology being exactly the reverse of what we are told should be a malignant corner. In those days we attributed the prevalence of the disease to drinking rain-water caught from the roofs of the houses and immediately run into galvanised iron or cement-lined tanks. Naturally the water was very soft, and to this day I have a notion that the idea is not wholly wrong and that there

is much in the contention that the constant drinking of demineralised water is provocative of cancer. At all events, it is a sounder proposition to my mind than the theory which attributed the disease to the presence of a microbe that nobody has been able to find.

With reference to the inoculation experiments, what are they worth? Small neoplasms or inflammatory nodules may arise, though I question if the first really do, but I know that when I read the results of the experiments the impression left on my mind was that the tests were a failure. Certainly the inoculations did not take in anything like a satisfactory manner and they did not set up cancer.

The certainty of cancer being a curable disease several years ago was brought to my attention through meeting with a singular instance of spontaneous recovery. If anybody had related the story to me I should have told him at once that he had made a mistake in the diagnosis and I always expect the same measure to be meted out to myself. I saw the case first in company with Dr. Lawrence of Melbourne. The man had had two operations performed upon him, one the ordinary V incision of the lip and the other a similar but more extensive proceeding very nearly on the site of the first cicatrix. The disease had returned, and when we visited him the right jaw had become extensively involved. His mouth was filled with the tumour, an infiltration had occurred—that is to say, the disease had extended to the sub-maxillary gland, so that no operation was admissible. That man, save that he shed his lower jaw piecemeal not as one sees in actinomycosis, where the bone shells—recovered perfectly and was alive eight years afterwards, when he was accidentally killed at a railway crossing of which he was the gate-keeper. During the interval I saw him repeatedly, though I never recognised him as my former patient, and it was only a few days before his death that I heard the sequel of the case. Happening to meet the widow—the wife then—she told me who she was, and related how the bone came away, and so forth. She was under the impression that we had done something to effect this cure. At all events, I learnt from this case that cancer is a perfectly curable malady. If it could only be found out what went wrong, the remedy was probably close at hand. Now about this time the columns of THE LANCET were filled with the accounts of myxœdema and its connexion with a gland that until the present had been considered of no value, an unimportant lump of tissue pertinent only to fetal life. In reading the discovery and the symptoms of thyroid disease I thought that I saw the likeness between it and cancer and that probably the two were allied to one another in very close relationship.

A large majority of the people who suffer from gall-stones die from malignant disease. Mayo Robson, to quote one authority, observes this, and I think he puts the percentage as high as 87. Others mentioning this fact write of cholesterine irritation as if the disease was an inflammatory one. How can cancer be the product of constant irritation? If such were the case other calculi than the smooth, round, greasy gall-stone should give rise to similar effects, and we know they do not. A renal concretion will disorganise the kidney, cause abscess, and play as much mischief as possible, but the last thing one associates with these lesions is cancer.

Cancer is not communicable and yet is auto-infective. I think that this is generally admitted; it requires no reference to authorities on my part. But what does it mean? It implies that A, a non-cancerous man, is protected against the disease which B, a cancerous man, has got; or, in other words, that A possesses and still retains something that B has lost. Thyroid gland secretion has some action in cancer. I gave it years ago when the tabloids were first introduced by Messrs. Burroughs and Wellcome on several occasions. As a rule, one might just as well administer peppermint water, but sometimes it has a surprising action. I remember one patient who was, I really thought, going to recover. After a time I lost sight of her. She made a marvellous improvement for some weeks whilst under my care, but funds running short she had to return home. I read of a case in THE LANCET in which recovery actually did take place under the thyroid gland treatment.

Let me now ask two questions, the purpose of which will shortly be seen. The first is, What occasions the peculiar and offensive smell in cancer? It is one *sui generis* and is never smelt except when the disease is active. It is not due to sloughing, for ether injections, though dreadfully painful

for half a minute or so, will entirely remove it and yet the process continues. Its disappearance is the first indication that an ulcerative cancer is healing, though it may take considerable time for the decayed tissue to come away. The next question I wish to ask, is, Why does a cancerous patient die? Why does he waste so? It is replied, "By septicaemia, pleurisy, the effects of tumour pressure." Yes, these are concurrent affections which may or may not cut short life, but if none of these happen and infiltration is not extensive he will die from exhaustion. But why? I operated once on the lip of a man, aged 32 years. In five weeks the disease returned in the cheek; he very sensibly refused further operation and in 10 weeks' time he died, the whole illness lasting four months. He had no pneumonia, no pleurisy, no rise of temperature beyond just a degree from the beginning to the end, no suppuration to speak of, no extensive transposition of cells, for none of the glands were involved, and yet the disease ran as rapid a course as I have ever seen it do. I could call to mind one or two other cases similar to this. What caused the wasting and exhaustion that preceded death? I must ask that three postulates may be granted to me, only the last of which will require any comments:—1. All secretions must have their uses. 2. Consequently the loss of any secretions, save such as are only provided for temporary requirements, e.g., milk, must mean some sort of disorder. Glandular provisions vary as their nerve-supply is stimulated or repressed, but there is always a certain limitation beyond which *plus* or *minus* must be followed by some derangement. 3. All reproduction is subject to control, or else given nutrition it would be indefinite. This law is as universal as that of gravitation and applies as much to the cell and the fibre as to anything else, be it a sheep or a salmon. Now, in obedience to this law there must be something that regulates the proliferation of the cell. It can only be a secretion, subjected to a higher power.

Again (1) ultimate tissue elements are cells and fibres; and (2) cancer is uncontrolled proliferation of the cell. Now if one ultimate element can lose its reproductive inhibition it stands to reason that the other can do the same. It is a natural consequence, and if it were otherwise nature would exhibit a partiality which she never elsewhere evinces, so that we should expect to find some disease that corresponds to cancer, and that is exactly what we have in myxœdema which is uncontrolled proliferation or cancer of the fibre. Consequently we have three forms of cancer (I think a fourth should be added, but let that pass for the pre-ent): (a) carcinoma, uncontrolled proliferation of the cells, derived from the hypo- and the epi-blast; (b) sarcoma, *idem*, ..... cells derived from the meso-blast; and (c) myxœdema *idem*, ..... fibre. Is not posterior mediastinitis a form of local fibre cancer?

When we evaporate bullock's bile—or that from a dog is perhaps better, on account of the latter being carnivorous—at a certain stage in the proceeding we notice the presence of a soap. Having separated the mucin and lecithin, and removed the colouring matters, there remains a very sticky reddish substance which consists of a bitter principle, animal gum, a soap, and, if the filtering has been done while the alcohol was hot, some cholesterine. Now, we always meet with cholesterine in its crystalline form—that is to say, when it has become a morbid product. Of course, in the economy it is in solution and is kept in this condition by its natural aqueous solvent soap. It is the loss of this soap that permits cholesterine to separate from the living cell and cell-cancer to start. The uncholesterine cell is the uncontrolled cell, and here, perhaps, comes in the connexion of this disease with the constant drinking of demineralised or rain-water. The red material referred to above is termed in text-books "sodium-glyco-cholate" and "sodium taurocholate." It does not matter what it may be called, its animal constituent forms a soap with the sodium salt. If the hands be washed with it it will soon be seen that it is a soap. The "Dictionary of Solvents" mentions soap as the solvent of cholesterine, but this was not shown to me until the patient in my second case had recovered. When I came first to think seriously about cell proliferation I thought the control might be cholesterine, and in one case I injected that substance dissolved in ether—a very thoughtless thing to do, I must admit, for of course when the ether is evaporated the crystal re-appears, is absorbed, carried into the blood current, and in this form is eliminated by the kidneys, turning the urine into a vivid red. Of course, benzine and chloroform cannot be employed subcutaneously and

it was a long time before it struck me that soap was the aqueous solvent. My first impression was that cholesterine was the control, that it was in some way lost and if one could restore it by the hypodermic method some good might accrue. Accordingly I dissolved, or thought that I dissolved, some crystals in soap and administered thyroid secretion, injecting at the same time, only in a different place, seven and a half grains of gum that had been crystallised in ether. I thought that by administering thus the whole of the bile secretion, if I got any results I could afterwards discard any constituent that was useless, testing each in its turn. (By-the-by the notion that one cannot inject animal gum is erroneous. I have used as much as 15 grains without the slightest effect, beneficial or otherwise. From this I conclude that it is only a vehicle and in the treatment of cancer of no consequence. But to proceed.) The first case on which I tried this solution was an instance of epithelioma of the face. The patient, a woman, aged 76 years, had had this ulceration more or less for two years and when seen by me it was nearly of the size of a florin. It had been operated on, I think twice, by Dr. Barrett of Glenferrie, a suburb of Melbourne. After one proceeding it had healed up for a space but it broke out again shortly afterwards. He had scraped it, cauterised it, and used electrolysis. These failing he kindly passed the patient on to me. The injection answered splendidly, the ulcer quickly taking on a healing action and in a month it was well. The next instance was one in the Austin Hospital for Incurables. This man had had half of his lower jaw removed, secondarily to the lip incision the whole of the side of the face. After the second operation I used soap and cholesterine, the same solution as before. All this time I was under the impression that the active agent was cholesterine and that I had the latter dissolved, but it could not have been so for I had not broken the crystal up and unless it be crushed it will not dissolve. I suppose it must have passed into suspension only, for the iodine and sulphuric acid test gave it beautifully. For six weeks this man improved marvellously, when I conceived a way of dissolving the crystal so that the soap really took up a considerable quantity of cholesterine and I innocently injected this new solution as an improvement on the other. The results were most disastrous. The disease returned with extraordinary rapidity, and in a short time he passed away without pain or much stench. I then got hold of a breast case in an old patient of mine who, on my explaining the nature of the case, gave me *carte-blanche* to treat her as I liked. I showed the case to my neighbour, Dr. J. Jamieson, before I commenced dealing with it. His expression was, "Well, there's no doubt about that," nor was there. There was a tumour of the size of an orange which had been painless until recently, when the patient began to get neuralgia in her arms. The tumour, which was of two years' growth, was firmly attached and the nipple was deeply retracted. I injected soap, in which I thought I had dissolved some cholesterine, but as I have said, I must have been in error, and gave thyroid. This time I discarded animal gum. In less than six weeks the whole tumour had disappeared, leaving a firm cicatrix, and this fibrous tissue in its turn dissolved, so that in three months after the commencement of treatment one would hardly have known that there had been any disease at all; a little nipple retraction was all that was left. As I do not belong to any medical society I showed this case privately to my friends. Well, naturally everybody remarked, "Was it cancer?" Notice the sequel. For 15 months the breast remained perfectly sound, when one day the woman returned and showed me a rather suspicious skin spot. I injected it and in a few days to my surprise a slough came away leaving a malignant, stinking ulcer of the size of a half-crown, with a very dense base. I must say, for my own part, that I was rather glad to see this, for it was an absolute proof, if anything was wanted to confirm my diagnosis. By the same treatment, that is to say, soap and thyroid, this breast has completely healed for the second time. I must claim this instance as the first primary cancer of the breast successfully treated. After this I got a case of epithelioma of the hand from Dr. J. H. McGee of Melbourne. By this time I thought that I had perfected my solution, getting so much as half a grain of cholesterine to dissolve in half a drachm of soap solution, but when I came to try it in this case I failed most signally. Adhering to the cholesterine I failed again in a breast, but towards the close of this case I recognised

one error, but too late to save the patient's life, for she passed away peacefully without pain or stench or any other discomfort. This was rather a hopeless case from the first, for besides the malignant disease she had renal trouble and an ununited fracture of the thigh, and she was very old and feeble. Again I failed in a case of general cancer, although this time I only used the soap solution, without thyroid. Then came a rodent ulcer in a young woman 26 years of age. It was of 11 years' duration, and had been twice removed and once grafted. It was situated right in the middle of the forehead. This patient completely recovered in six weeks under the soap solution and thyroid per os. A big scar remained, and as it was healing the treatment was rather painful. Then I failed in a non-infiltrating epithelioma, again on the side of the nose and cheek. Here I did not give the thyroid, for with the peculiar wilfulness of some of the patients in these cases the man would not take it, but I do not know that I should have succeeded, for in neither of the two cases where the growth has started from the bone have I managed to effect a recovery. Then I had a case of epithelioma of the hand, a small thing of the size of a florin perhaps, and seemingly not attached to the bone. This did beautifully. The next case was an epithelioma of the tongue; the soap acted excellently, but on account of the extensive heart disease from which the patient, an old man, suffered and his generally exhausted state, I dared not use thyroid. I tried the general injections at first without effect, but he collapsed so after these that I had to abandon them and to revert to local insertions. He died, but absolutely without pain or smell; he just slipped into death, though extremely wasted, as a child will fall asleep in his mother's arms—a beautiful euthanasia. Fancy one dying from cancer of the tongue without pain or stench. The same happened in another very advanced instance in which the tongue, lower jaw, palate, and tonsil had been removed. The action of the soap was here most marked, although the man has not recovered, though as I write these words he is not dead, but on account of so much of his face having been removed the taking of food is a great difficulty. When I first saw him the whole of the interior of the mouth and cheek was one mass of cancer. It was extraordinary how he could live with such an extension of the disease. All smell and discharge have gone and he suffers no pain. I look on this as my champion case. I must instance one other case of recurrent epithelioma in which the patient died from an over-dose of soap solution. Until quite recently I thought that this preparation was a perfectly innocent one, of which any quantity might be injected with impunity. But such is not the case, for in the course of the treatment I gave this man two drachms at one time and he collapsed and succumbed in 24 hours. The soap solution should be just thick enough for blowing bubbles. Of course, it should always be boiled first and delivered warm. It is apt to occasion very painful spots, which look exactly as if an abscess were going to form, but if they are left alone in a couple of days all the tumefaction disappears, but meanwhile they are rather tender. Still they never do come to pus. I rather like a biggish inflammatory areola. Never more than a teaspoonful should be administered at a time, for, as I have related, injections are not absolutely without danger. If more is given shivering and collapse may occur. Another precaution is never to inject in one's own house unless means can be provided for the patient to lie down for an hour or two afterwards. To anticipate the shivering a morphia injection is advisable. It is always well, I think, to employ an anæsthetic, nitrous oxide for preference. If something of the sort is not used patients dread the needle and accordingly suffer in expectation and shirk treatment. At first I inject every other day and as the case improves less frequently until once every week or 10 days suffices. A very good soap to use is the superfatted soap prepared by Messrs. Allen and Hanburys, but for that matter common yellow bar soap will do. A bit should be dissolved in boiling distilled water and then strained through silk or closely woven calico. There are always some particles of dirt which might go through the needle and easily set up an abscess. In the many scores of injections which I have given I have only on two occasions set up an abscess. I have never yet managed to effect much good where the growth or ulceration started from the bone.

If I were asked what is malignancy I would reply, It is the crystallisation of cholesterine from the living cell. I

do not imply that there is any deficiency of cholesterine in the economy, but the cell has acquired the habit of passing it out of solution. That cholesterine in this disease is at fault the smell alone shows and this is why ether injections—shockingly painful—will deodorise an ulcer so well and for a time give such satisfactory results in respect to sweetness, but the odour returns, not, however, for a day or so. I once went very much astray with this will-o'-the-wisp. In carcinoma both tissue elements are represented, so the thyroid secretion is imperatively indicated, and I believe that the sole action of this body is to control the proliferation of the cell and that its action on metabolism is a snare and a delusion.

In conclusion, let me add that I hope some of the readers of THE LANCET will, in good faith, give my treatment a trial. It is rather in embryo, but in my hands it has given results far better than I ever anticipated.

Melbourne.

## A COMPLICATED CASE OF PLACENTA PRÆVIA.

By JOHN HOOLE, M.R.C.S. ENG., L.S.A.

THE patient was a married woman, aged 38 years. She had had six children born alive, and with the exception of the fourth pregnancy all her labours had been normal. At the fourth pregnancy the child presented in an abnormal position and the medical man had to resort to turning to deliver her. On July 13th, 1900, about 8 P.M., I received a telegram requesting me to attend the patient, who lived at a distance of five miles. I was told, on my arrival, by an old midwife, that the patient had gone her full time, but that about 4.30 P.M. of the same day she had been seized with violent pains in the abdomen; this was accompanied by profuse hæmorrhage which had continued. Also, that two months previously, some hæmorrhage had occurred which continued more or less until the present time. I was informed that the patient had persistently refused to see a medical man.

I found the patient in bed, lying on her back, in an upper room of a thatched cottage. She was blanched, restless, and slightly delirious, and muttering abuse at the midwife. Her pulse was hardly perceptible, and the abdomen on inspection was wider and flatter than in normal cases of pregnancy. The external genitals were obscured from view by a large blood-clot, which was continuous into, and entirely filled, the vagina. The bed-clothes, bedding, and floor plainly told that profuse hæmorrhage had occurred. On examination the os was dilated sufficiently to allow the tips of two fingers to be introduced, but it was rigid and unyielding. The placenta was completely presenting and there was slight hæmorrhage into the vagina. No uterine action was taking place. The husband, being informed by me of the serious condition of his wife, sent for Dr. B. E. Dalison of Puddletown to assist me. Pending the arrival of that gentleman I administered chloroform and separated the placenta from the uterine wall with my two fingers as far as I could reach in a circle; this necessitated much force to dilate the os. I also gave repeated enemata of hot saline solution. On Dr. Dalison's arrival, after consultation, we agreed, considering the great loss and serious condition of the patient, to deliver her with forceps, as a round, hard substance could be indistinctly felt through the placenta which it was thought might be the head of the child. The patient being again put under chloroform the forceps were applied, force being used to introduce them. They were locked, but on traction only a large piece of the placenta was brought away. On further examination a leg was felt; this was brought down and after considerable time and great difficulty, in which severe force was used, a dead child was born. The remainder of the placenta was removed and the uterus contracted without any more hæmorrhage. Small quantities of hot milk with brandy were administered to the patient at intervals during the night. I attended her daily and she was douched with solutions of perchloride of mercury. The temperature never rose above 102° F. and in a fortnight she was convalescent, taking appropriate nourishment and a mixture of quinine and iron.

If I may suggest the points of interest in the case, they are the great loss of blood, the considerable force that had to be used in dilating the os, first by our fingers and

afterwards with forceps, together with the rapid dilatation of the passages in delivering the child, and the subsequent absence of any nervous or septic symptoms.

Throgmorton-avenue, E.C.

OF

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

#### ST. BARTHOLOMEW'S HOSPITAL.

##### A CASE OF DEPRESSED FRACTURE OF THE SKULL FOLLOWED BY OCULAR SYMPTOMS.

(Under the care of Mr. A. WILLETT.)

SYMPTOMS connected with sight are rare in head injuries, if we put aside paralyses of the extrinsic muscles of the eye. In the case recorded below the left occipital lobe was lacerated, and as a result there was a partial right hemianopia. This is the condition that might have been expected from a lesion of the occipital lobe on the left side. The great improvement in the extent of the field of vision is striking. For the notes of the case we are indebted to Dr. G. V. Bull, late house surgeon.

A man, aged 48 years, was, on March 14th, 1901, admitted to St. Bartholomew's Hospital, under the care of Mr. Willett, having fallen 30 feet down a lift shaft and struck the back of his head (apparently on an edge). On admission he was conscious but did not remember his accident. He was cold and collapsed and was bleeding profusely from a wound in the occipital region in which depressed and comminuted bone could be felt. Both pupils reacted and there was no sign of paralysis. The pulse was 120 and regular and the temperature was 97° F. No injury to the spinal column could be made out. The wound was examined three hours later, a flap of skin being turned back on the left side of the skull. A gap was then found in the skull extending from the occipital protuberance upwards and slightly to the left for about three inches and being from one-third to two-thirds of an inch wide. In this gap there were fragments of bone and lacerated brain substance (left occipital lobe); the fracture extended as a linear fracture both upwards and to the base. The superior longitudinal sinus was intact, as was also the tentorium. The fragments were removed by forceps and one piece of bone at the upper angle was elevated. The wound was irrigated with boric lotion, the skin was sutured with fishing gut, and a wire drain was inserted at the lower end. During the night the patient was very restless and the pulse was weak and very irregular. On the next day he was better, the temperature being normal and the pulse 120 and regular. He complained of great pain in his back and was unable to pass urine. His knee-jerks were much exaggerated, but there were no ankle clonus and no affection of sensation. The wound was dressed on March 22nd and was found to have healed; the scar was pulsating strongly. On April 15th he was up and walking about. He was then able to pass urine. He was free from headache and from giddiness except on sudden change of position. He complained of inability to see objects to his right. No change in the fundus was made out, but Dr. Bull was unable at that time to test him with the perimeter. On April 20th the patient left the hospital and was not seen again till July 16th. He was then improved in every way and he said that his sight was better and that he could read better. The perimeter showed a partial right hemianopia, the lower quadrant of the fields of vision being lost. There was no change in the fundus. The pupil did not react when light was thrown on the affected part of the retina. He complained of pulsation in the scar and weakness in his back. On Sept. 12th Dr. Bull saw the patient again. He still complained of the pulsation which

he felt but did not hear, but it was less marked. The perimeter showed improvement, especially in the right eye, and there was no change in the fundus.

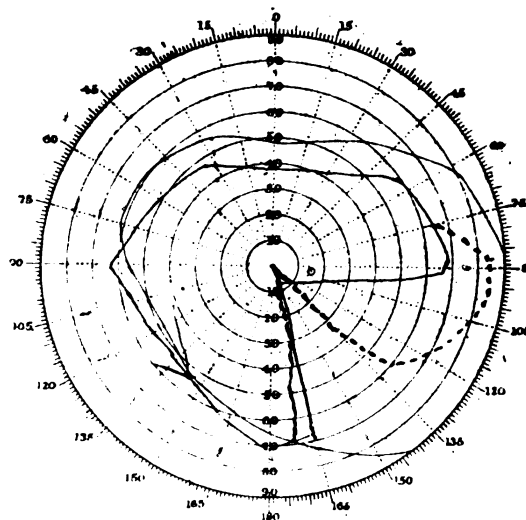

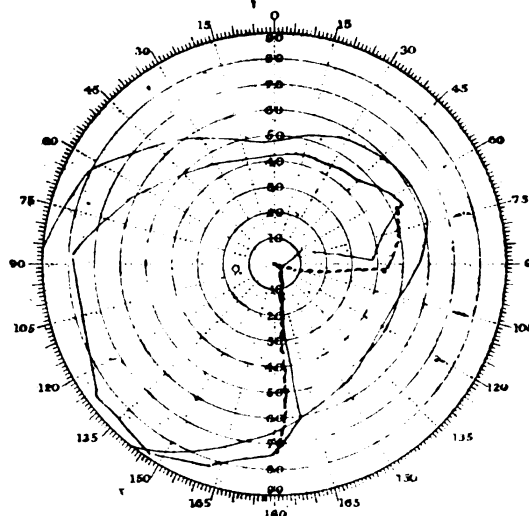

FIG. 2.

LEFT

The continuous line represents the field of vision on July 16th and the interrupted line that on Sept. 12th.

*Remarks by Dr. BULL.*—The case is interesting on account of the almost complete recovery. The patient is now able to do six hours' light work a day and may reasonably hope to improve still further. I am indebted to Mr. Willett for permission to record the case.

#### BOLINGBROKE HOSPITAL, WANDSWORTH COMMON.

A CASE OF ACUTE DOUBLE INTUSSUSCEPTION IN A FEMALE  
INFANT, NINE MONTHS OLD; OPERATION 24 HOURS  
AFTER ONSET OF SYMPTOMS; RAPID RECOVERY;

REMARKS.

(Under the care of Mr. THOMAS BRYANT.)

RETROGRADE intussusception is much rarer than the ordinary variety, and in the following case both forms were present. The occurrence of these two varieties in the present instance affords an insight into the method of

production of intussusception. In both forms in this case the transverse colon ensheathed the neighbouring bowel, so evidently the transverse colon had become for some reason greatly relaxed, so as on the one hand to allow the cæcum to pass into its interior, and on the other to slip over the descending colon and rectum. It is highly improbable that any inflation or injection can ever reduce a retrograde intussusception. By employing such methods valuable time is wasted and the exhaustion resulting from these attempts cannot but materially diminish the chance of recovery from a subsequent operation. This case is a forcible argument in favour of primary laparotomy for intussusception.

On August 7th, 1901, a female child, aged nine months, was sent into Bolingbroke Hospital, Wandsworth Common, by Mr. R. C. Kirby of Earlsfield-road, Wandsworth, with what he diagnosed as an intussusception. The child had been healthy and had not been weaned. The bowels had been regular. The day before admission at 3 P.M. sickness had suddenly appeared and had returned each time the child took the breast; four hours later the infant passed blood from the bowel mixed with mucus, and accompanied with slight straining, and these symptoms persisted at short intervals up to the time of admission.

On admission these symptoms were as described and the infant did not seem to be in much pain, nor was she seriously collapsed; one tumour was perceptible above the umbilicus and a second one in and above the left iliac fossa; both tumours appeared to be moveable. The abdomen was not very tense. Nothing could be felt in the lower bowel on a rectal examination, although the finger when withdrawn was covered with blood and mucus. Mr. Kirby's diagnosis of intussusception was confirmed by Mr. Bryant, who happened to be at the hospital when the infant was admitted, and an immediate operation was decided upon. It was performed at three o'clock on August 7th, about 24 hours after the first onset of symptoms, with the infant under the influence of chloroform. A median incision below the umbilicus was made and an elongated tumour was felt occupying the position of the left half of the transverse colon down to the rectum, which could not be brought into view without increasing the incision to the extent of an inch above the umbilicus. The small intestines were kept back with difficulty by means of flat sponges. When the colon was exposed and examined two distinct intussusceptions were clearly found to be present. One was of the cæcal variety, involving some inches of the ileum, the cæcum with its appendix, and the ascending colon, which were invaginated into the transverse colon, and reduced without difficulty by pressure upon its distal end and gentle traction at its proximal end, the body of the cæcum being very oedematous and hard. The second intussusception seemed to be in the descending colon and some four inches of empty colon separated the two seats of trouble. In the second intussusception a curious condition existed, for it was quite clear that the colon itself had as it were slipped over the descending colon and the rectum and had so produced an invagination of the upper portion of the rectum into the colon. This was reduced like the one described by manipulation from above, helped by slight traction upon the rectum at the brim of the pelvis, the proximal or cæcal end of the intestinal tract being invaginated in the usual way into the colon in the one case, and the distal or rectal end of the bowel being invaginated into the colon in the other. The invaginated structures were in both situations highly congested and oedematous, but otherwise they were normal. The parts involved were then cleansed and the wound was carefully closed with sutures, the peritoneum being included with all the other tissues in each stitch. The abdomen was firmly bandaged and the infant was allowed to take the mother's breast within an hour. The child had stood the operation well and was during the operation kept warm with blankets. Directly after the operation an enema of two ounces of warm milk was administered. No symptom subsequently appeared to cause anxiety. The temperature rose to 102.6° F. on the night of the operation but it steadily fell, and on the third day became normal. No vomiting occurred and on the day after the operation the bowels acted four times. There did not seem to be any pain. On the fourth day the child was fed by the bottle on milk-and-water, as the mother's milk seemed to be poor. On the sixth day the wound was dressed for the first time and was found to have healed. Everything subsequently went on steadily to a convalescence and at the end of three weeks the child

was taken home, and when these notes were written two months later she was quite well.

*Remarks by Mr. BRYANT.*—This case is full of interest, and from the contrast of the two varieties of intussusception which coexisted is somewhat uncommon. The higher or cæcal variety presented no unusual conditions, but the lower form was most irregular, for in it the descending colon had evidently slipped over the higher portion of the rectum and had thus invaginated it. This fact also explains why in the case recorded there was but little tenesmus and why nothing abnormal could be made out from a digital rectal examination; for the tenesmus, which exists as a rule in the common form of intussusception and which is evidently due to the expulsive efforts of the ensheathing portion of bowel to expel the invaginated, was in the case under consideration non-existent. With respect to the treatment which was adopted the case reported must tell very strongly in favour of early operation, and Mr. Kirby must be cordially congratulated upon his action in sending his patient at once to the hospital for treatment, and in thus enabling me within 24 hours of its commencement to bring about by an immediate operation a reduction of the two intussuscepted portions of bowel, which it is very probable no other measure, such as inflation by air or the injection of water, could have effected, with its accompanying rapid and sound recovery. Such a case as this in an infant only nine months old terminating so satisfactorily, without one single symptom which could cause anxiety, cannot do otherwise than strengthen the view which I strongly hold that a strangulated intussusception should be dealt with, like a strangulated hernia, by immediate operation, and that no valuable time should be wasted by the adoption of any temporising measure. I am indebted to Mr. K. B. Alexander, acting house surgeon, for the notes of the case.

### LEEDS GENERAL INFIRMARY.

#### A CASE OF ACUTE INTESTINAL OBSTRUCTION; REMOVAL OF THREE FEET OF GANGRENOUS GUT; RECOVERY.

(Under the care of Mr. W. H. BROWN.)

THE amount of bowel which may be resected without undue interference with the processes of digestion and absorption is difficult to determine. Dreesman<sup>1</sup> collected 26 cases in which more than a metre of small intestine had been removed, and six successful cases have been recorded in which more than two metres have been excised.<sup>2</sup> Four of these six cases had digestive disorders as a result of the removal of so much bowel, but the younger the patient the more likelihood is there that compensatory hypertrophy may occur and functional disturbances be avoided. In the case recorded below three feet of bowel were removed, so that no digestive troubles are likely to occur. The question of immediate suture of the cut ends of the bowel after resection for gangrene or the temporary formation of an artificial anus must always be determined by the general condition of the patient. The case also illustrates the value of continuous infusion of saline solution during an operation. For the notes of the case we are indebted to Mr. F. Stansfield, acting house surgeon.

A boy, aged 16 years, was admitted into the Leeds General Infirmary on March 29th, 1900, suffering from suppurative appendicitis. The abscess was opened and drained and he was discharged well on May 30th, 1900. On July 1st of the present year he was re-admitted with well-marked signs of internal strangulation. The general condition was very bad. Intravenous injection of saline solution was commenced at the time of the opening of the abdomen and continued throughout the operation. So soon as the peritoneal cavity was exposed a large loop of gangrenous small intestine was seen; this was brought outside the abdomen. The cause of constriction was a band fastening the bowel down to the side of the pelvis just beneath the site of the appendicular abscess. The band was cut through, the gangrenous bowel was cut off, and the severed ends of the healthy intestine were stitched to the skin. The pelvis, which was filled with dark, offensive fluid, was washed out and drained with a glass tube. The boy made a good recovery and on August 14th the integrity of the intestinal canal was restored

<sup>1</sup> Berliner Klinische Wochenschrift, 1899, No. 16.

<sup>2</sup> THE LANCET, Jan. 27th, 1900, p. 218.

by simple suture. The patient made a rapid recovery and is now (Sept. 24th) quite well.

*Remarks by Mr. BROWN.*—I have never before met with a case in which there was so much destruction of tissue where recovery followed. The condition of the patient was so bad that I did not expect him to survive the operation and but for the employment of continuous transfusion I am sure that he would have died on the table. Whether the pre-existing appendicitis was the cause of the strangulation I cannot say, but the point of constriction closely adjoined the former abscess. I did not attempt an immediate joining up of the severed bowel for two reasons: (1) the condition of the patient was far too desperate to permit of a prolonged manipulation; and (2) I am satisfied that in such cases it is far better to provide a free exit for bowel contents by making an artificial anus than to attempt to restore the continuity of the intestinal tract by any mechanical contrivance which lessens at the most critical time the calibre of the intestine.

## Medical Societies.

### OBSTETRICAL SOCIETY OF LONDON.

#### *Leukæmia and Pregnancy.—Exhibition of Specimens.*

A MEETING of this society was held on Oct. 2nd at 20, Hanover-square, W. Dr. PETER HORROCKS, the President, being in the chair.

Dr. G. E. HERMAN read a paper on Leukæmia and Pregnancy, reporting a case of his own, and 12 other cases already published elsewhere. Critical examination showed that in five of these latter cases the evidence of leukæmia was deficient. There were, therefore, only eight cases from which to draw conclusions as to the mutual influences of pregnancy and leukæmia. These eight cases agreed in the following points: (1) the presence of an enlarged spleen and liver caused patients with leukæmia to suffer more from the abdominal distension of pregnancy than healthy women; (2) the symptoms of leukæmia were aggravated during pregnancy; (3) in pregnancy with leukæmia there was a great tendency to abortion or premature labour; (4) death sometimes quickly followed the termination of pregnancy with leukæmia; and (5) if the patient survived the termination of pregnancy great improvement took place. Dr. Herman concluded from these facts that in pregnancy with leukæmia the induction of premature labour or abortion was indicated as a therapeutic measure.

Dr. AMAND ROUTH remarked that the paper was one of special value. As Dr. Herman had remarked, the combination was one of a blood dyscrasia with a condition causing pressure from the presence of a large spleen. It was therefore different from ordinary blood dyscrasias such as in other specific diseases and also from conditions causing simple pressure such as the presence of an ovarian tumour, and these facts imparted a special feature to the condition. There was a point not alluded to in the paper that he would like to ask Dr. Herman about—namely, as to the effect of leukæmia on the fœtus in utero. A good deal had been written on the transmission of diseases to the fœtus and it appeared that a process of filtration might be effected by a perfect chorionic epithelium, whilst a defective epithelium would allow of the transmission of disease to the fœtus. This was illustrated by cases of twins in which one fœtus was healthy and the other was affected with the same disease as the mother, such as cholera, glanders, malaria, erysipelas, and many of the acute specific fevers. Had any of the children of these leukæmic women had their blood examined after birth? He quite agreed with Dr. Herman's conclusion that premature labour should be induced when symptoms threatened to become urgent without waiting for serious developments.

Dr. A. L. GALABIN had met with one instance of the association of pregnancy with a disease as to which he was rather doubtful whether it should be classed as splenic leukæmia or so-called pseudo-leukæmia. There was a large splenic tumour reaching as low as the crest of the ilium, with extreme anæmia and tendency to hæmorrhage. But the relative proportion of leucocytes in the blood was only moderately increased, not to that extreme degree which was seen only in leukæmia. He had watched the lady for several years, and under treatment with arsenic and large doses of quinine the tumour somewhat diminished in size and the general condition improved. On one occasion she came for

consultation, being about three months pregnant, and reported herself as feeling better. The spleen also seemed to have diminished in size since the pregnancy. He had had no experience of the effect of pregnancy on such a condition and feared grave results from the tendency to hæmorrhage, but in view of the actual improvement he did not advise interference at that time. The patient shortly afterwards went to France, and there it was decided to induce abortion before the child had become viable. He did not know whether the reason was the abdominal distension or the general symptoms. The result was that the patient died undelivered, and, so far as he could learn from the friends, the cause of death was hæmorrhage.

The PRESIDENT was surprised to hear how little hæmorrhage there was from the uterus in these cases of miscarriage during leukæmia. Hæmorrhages were common in this disease, and probably that accounted for the miscarriages, the bleedings taking place in the placenta and so destroying the ovum or fœtus. In some cases hæmorrhage occurred some time before the actual miscarriage and thus allowed certain changes to take place which prevented flooding. He understood Dr. Herman to advocate the induction of miscarriage or labour as soon as the presence of leukæmia was discovered, without waiting for any bad symptoms.

Dr. HERMAN said that the infant was not affected in maternal leukæmia. He advised induction of premature labour or abortion as a therapeutic measure only in cases in which the symptoms caused suffering and were aggravated after the onset of pregnancy.

The following specimens were exhibited:—

Dr. GALABIN: (1) A Sub-peritoneal Fibro-myoma; and (2) a Sarcoma of the Uterus.

Dr. HERBERT SPENCER: An Ovarian Cyst which ruptured three days after labour.

Dr. WILLIAM DUNCAN: (1) A Fibro-myoma of the Uterus; and (2) a Papillomatous Cyst of the Broad Ligament.

Dr. H. R. ANDREWS: (1) A Fibro-myoma of the Ovary; and (2) a Melanotic Sarcoma of the Ovary.

Dr. ROBERT WISE: A Volsella Forceps for Friable Cervix.

The specimens were discussed by Mr. RUMLEY DAWSON. Mr. ALBAN DORAN, the PRESIDENT, Dr. F. J. MCCANN, Dr. AMAND ROUTH, and Dr. T. G. STEVENS.

**TORQUAY MEDICAL SOCIETY.**—The new session was opened on Oct. 4th by an address from Dr. T. D. Acland, physician to St. Thomas's Hospital, on the Recognition of Certain Intra-thoracic Conditions which Justify Surgical Treatment. The address, which was illustrated by diagrams, was listened to with great interest by a representative gathering of the medical men of Torquay and its neighbourhood, the subject chosen being one which specially appealed to the professional instincts of the medical men of a south coast health-resort. Although coming from a physician it really was a plea for surgical measures in the treatment of certain conditions of intra-thoracic disease after a correct diagnosis had been made, the lecturer admitting, however, that in a few cases a correct diagnosis during life was not always possible.—In the evening Dr. Acland was entertained at dinner at the Queen's Hotel by the members of the society, Dr. William Powell, the President, being in the chair, and a most enjoyable evening was spent.

**GLASGOW SOUTHERN MEDICAL SOCIETY.**—The opening meeting of the session was held on Oct. 3rd in the rooms of the Southern Medical Club, 18, South Portland-street, Glasgow, Dr. William Watson being in the chair. There was a large attendance of members and after some formal business had been transacted the meeting proceeded to the election of office-bearers, with the following result:—Honorary President: Dr. Thomas McCall Anderson. President: Dr. John Stewart. Vice-Presidents: Dr. Duncan Macgillivray and Mr. Thomas Richmond. Treasurer: Dr. Andrew S. Tindal. Secretary: Dr. John Fraser Orr. Editorial Secretary: Dr. Andrew Wauchope. Seal-keeper: Dr. Matthew Dunning. Extra Members of Council: Dr. John Lindsay Steven, Dr. Hugh Kelly, and Dr. James Hamilton. Court Medical: Dr. William Watson, Dr. Ebenezer Duncan, Dr. Robert Pollok, Dr. Thomas Kirkpatrick Monro, and Dr. Alexander Napier. Representative to Victoria Infirmary: Dr. Charles E. Robertson.

**ÆSCULAPIAN SOCIETY OF LONDON.**—A meeting of this society was held on Oct. 4th, when Dr. Arthur T. Davies, the President, gave his inaugural address, taking for

his subject "Thomas Sydenham, M.D., L.R.C.P., 1624-1689." A full account of his life-work, his friends, his theories, and his treatment was listened to with much attention and interest.

## Reviews and Notices of Books.

*Memoirs and Letters of Sir James Paget.* Edited by STEPHEN PAGET (one of his sons). London: Longmans, Green, and Co. 1901. Pp. 438. Price 12s. 6d. net.

MR. STEPHEN PAGET has done his work as editor so well that we have a book entirely worthy of the noble name which it commemorates, even where it is not from the pen of Sir James Paget himself. Nothing has been added that is unnecessary, nothing included that is uninteresting, and at the end of this book we are left with a clear continuous idea of a long and beautiful life. Our impression is as definite, as inclusive, and as exquisite as must have been that left by one of Sir James Paget's own lectures on a favourite subject. The biography of a great man is always the finest and most inspiring reading, and we can imagine no book more likely than this to fire the best ambitions of a young, or to sustain the labours of an older, medical man. Though only in part intentionally and in part incidentally autobiographical the final result of reading these memoirs and letters is a perfect idea of a singularly consistent and successful career. Yet it must not be imagined that Paget's success came easily or from the first. The consistency was in his unwavering determination and incessant work, a consistency that bore him with scarcely any intervals but those of illness through more than 60 years of effort. Besides the strength of will and power of work we are left impressed with the clear sense, the humour, the deep kindness, the honourableness, and the religion of Paget. There are few lives which bear as well as his the scrutiny of the private or the public observer. We see him through this book as devoted to his home as to his hospital, and as beloved and respected by his family as he was revered and appreciated by his pupils and his patients. James Paget was almost as fortunate in his parentage as were his own children in theirs. Of his father he writes in his Memoirs. "He had a very large family and as long as he could he treated them very generously and educated them expensively. I should give a very wrong impression of my father if I were to speak of him only as a man of business. He was in this an admirable example; punctual, constant in work, perfectly fair, liberal, and honest; even when he failed no one blamed him. But he was besides a thorough gentleman—cheerful, well-mannered, peace-loving, and hospitable; perfectly temperate, when frequent drunkenness was not deemed vile; refined in conversation, even when cursing and nastiness were scarcely vulgar; and a lover of all that was simply beautiful in literature and art." In writing of his mother's father, "a kind of self-elected fine gentleman," Paget shows some of that aptitude for description and that high humour which appear so often in his letters and which must have given much of their irresistible attraction to his lectures and to his private conversation. He writes of his grandfather: "I just remember him—a fine old man, grave and dominant, for whom all his daughters had so profound respect that, although I never heard of his having said or done anything very wise, I never heard of their having wished for anything less or other than he did. And their respect for him did not diminish when he was dead; though he left them nothing, unless it were the gout, of which my inherited share has had great influence on my life." Paget's mother was a worthy companion for his energetic and hospitable father. Nine of her 17 children grew up to

full age. "She took the close charge and guidance of them all; she managed all household affairs; she collected 'everything'—autographs, seals, caricatures, shells, corals and agates, old china and glass, and curiosities of all kinds; and all her collections were orderly arranged and labeled in her own fair hand. She wrote I know not how many scrap-books and filled I know not how many albums." Till the age of 13 years James Paget was at a school which cost his father 8 guineas a year. At the age of 16 years he was so possessed of a desire to enter the navy that the uniform was actually bought, and it was only at the last moment that his mother's entreaties against letting him leave home prevailed. "I cannot imagine a happier escape," he writes, "for I cannot think of a calling for which I should have been more utterly unfit than for His Majesty's navy at that time." This was in 1830. The navy being abandoned young Paget was apprenticed "to an active, energetic, and well-educated practitioner in the town" of Yarmouth. Five years was the term of apprenticeship then required, at the end of four and a half of which he was to be allowed to go to hospital study in London. There is some pertinent criticism of the system of apprenticeship as compared with modern medical education. Its advantages, he says, were greater than is now commonly supposed. Many things of great utility in after-life could be thoroughly learned—things of which the ignorance is now a frequent hindrance to success. The period was, however, too long and the necessary daily work dull and at times tedious and apparently useless. As an apprentice Paget experienced an epidemic of Asiatic cholera. It is hard to remember anything of the methods of practice then generally used, he says, which is still instructive; the principles were deemed sure whatever consequences might ensue from observance of them. His apprenticeship gave opportunities for the study of botany and of this Paget writes: "I think it impossible to estimate too highly the influence of its study on the course of my life. It introduced me into the society of studious and observant men and gave me an ambition for success or at worst some opportunities for display in subjects that were socially harmless; it encouraged the habit of observing, of really looking at things and learning the value of exact descriptions."

Besides botany Paget taught himself French and learned to sketch. Of his educational work at this time he says: "Its immediate utility was too little, its indirect utility too great, to be told. The knowledge was useless; the discipline of acquiring it was beyond all price." It was at this time when he was 20 years of age and shortly to enter St. Bartholomew's Hospital that he published with his brother Charles a "Natural History of Yarmouth." Of the years of pupilage at St. Bartholomew's Hospital space does not permit us to tell much, but there is no part of the book better worth reading for an insight into what work means to men of Paget's stamp or for a glimpse of his ardent friendship and of his quick appreciation of character in companions or teachers. Throughout the book we find indications of Paget's keenness of insight and correctness in estimating the persons with whom he came into contact. Probably no quality was of greater value to him in later years of practice. The next chapter of the memoirs, Waiting-time, 1836-43, contains a record of hard work at teaching and writing and a scantiness of remuneration that should console the struggles of any young medical man. His annual income from practice at this time never exceeded £23 13s. and for the curatorship of the hospital museum he received £40 a year. He was now engaged to be married to the lady who after seven years became his wife, and, though the prospect of enough to marry on was then distant, his letters show a cheerfulness, a spirit, and a determination that seem justly to give an instinctive trust in the future to such men as James Paget.

Besides teaching, Paget was at this time constantly writing and reading and he taught himself German and Dutch. In 1843 he became lecturer on physiology at St. Bartholomew's Hospital and the first dean of the medical school. For the next eight years he lived in the hospital. During this time he became professor of surgery and anatomy at the Royal College of Surgeons of England and assistant surgeon to St. Bartholomew's Hospital.

In May, 1844, he married and "began to enjoy that happiness of domestic life which has lasted without a break for 39 years." There is no more attractive passage in this book than one describing Paget at work at home. He had the rare talent of being able to read and to write in a room where the rest of his family were otherwise occupied, and seemed to keep up at the same time a lively interest in what they were engaged upon or talking of, putting a word now and then into their conversation whilst busily engaged with papers and books at his own particular bit of the table. As a lecturer and public speaker Paget has had few equals in his own profession, and the memoirs contain interesting pages in which he discusses the value of this power and the best methods of exercising it. He counsels both the learning of speeches by heart and the practising of the power of speaking offhand. The consciousness that this can be done in case of need he found a wonderful help to the memory in that it diminished the fear of utter failure. *A propos* of lectures, he recalls Abernethy's historic utterance on entering his class-room full of students, "Good God, gentlemen, what will become of you all?" Paget, too, was impressed with the immense responsibilities of medical practice. He held it the bounden duty of medical men to make themselves as efficient as possible, and one of his favourite themes was the possibility—further, the necessity—of combining science with practice. In 1851 he resigned the wardenship of the College at St. Bartholomew's, and then private practice really began. It grew now steadily till, when at its height, an income was reached of £10,000 a year. Reflecting on the causes of success and failure Paget writes: "Anyone with a safe knowledge of his profession, free from the faults of habitual idleness, unpunctuality, incivility or unbusinesslike conduct, may be as certain of success in the practice of medicine or surgery, or both, as in any other business in life." Speaking, however, of the risks of professional life he reflects that had he died before 47 years of age he would have left wife and children in extreme poverty. The memoirs were written in the years 1880-85, when Paget was between 60 and 70 years old, and deal mainly with his early life. The latter years of great success, numerous friendships, and constant work in practice and on public and professional bodies are best appreciated by reading the second half of the book which contains the letters. Space will not permit us to deal adequately with the many professional questions discussed in these letters or with the abundance of delightful personal anecdotes and experience that they tell. We recommend their perusal to every one of our readers. Whether on account of his wisdom in all conduct of affairs or for the honourable and dignified view he took of life, whether for his insight and honesty in dealing with patients, or his indefatigable labour and interest in all that concerned his own profession, no medical man should fail to make himself familiar with the character and example of Sir James Paget.

*Scientific Memoirs by Medical Officers of the Army of India.*

Edited by Surgeon-General ROBERT HARVEY, M.D., C.B., LL.D., Director-General, Indian Medical Service. Part XII. Simla: Government Central Branch Press. 1901. Price 5 rupees 12 annas.

THESE scientific memoirs by medical officers of the army of India serve to illustrate a matter on which we dwelt very recently as to the favourable position in which army medical

officers are placed for observation and experiment and for cultivating natural science, into the fields of which they could but peep at the beginning of their medical studies. The present part of these memoirs contains six contributions from medical officers of the Indian Medical Service. A brief enumeration of their titles will show how wide and varied is the view open to medical officers for scientific study and observation. There are two papers upon botanical subjects by Major D. Prain, I.M.S., the superintendent, and Lieutenant A. T. Gage, I.M.S., the curator of the Royal Botanic Gardens, Sibpur, near Calcutta, and one on Zoological Gleanings from the Royal Indian Marine Survey Ship *Investigator* by Major A. W. Alcock, I.M.S., superintendent of the Indian Museum and Professor of Zoology in the Medical College of Calcutta, formerly surgeon naturalist to the Indian Marine Survey. In addition to these there are some important contributions dealing with questions of medical or sanitary science, such as one by Captain C. F. Fearnside, I.M.S., on Inoculation of Malaria by Anopheles; Some Observations on Spirillum Fever as seen in the Monkey, by Captain George Lamb, I.M.S., of the Research Laboratory, Bombay; and a contribution by Major Ernest Roberts, I.M.S., on Some Practical Methods of Sanitation in India, with Special Reference to Cantonments. With the last-named paper we have already dealt at some length.<sup>1</sup> A Leguminous genus *Afzelia* was founded by Smith in 1798 for a tropical African tree, but since Smith wrote no one has been able to find a plant exhibiting all the characters that he attributed to it. The paper by Major Prain is a learned and exhaustive one on the Characters and Relationships of *Afzelia* (Smith). The Zoological Gleanings by Major Alcock were well worthy of being collected and classified and of being published as a supplement to the Summary of Deep-sea Zoological Work which appeared in these memoirs in 1899. They contain much information and many curious and suggestive observations of scientific interest. We notice that Captain Fearnside in the practical conclusions of his paper on Inoculation of Malaria by Anopheles dwells very forcibly upon the great practical—indeed, in his opinion, insuperable—difficulties that exist in the way of ridding India of the anopheles and in the application of prophylactic measures to the native population of that country. His view is "that the malarial parasite is trimorphic and that there is a phase (extra-corporeal) yet to be discovered." The contribution on Spirillum Fever as seen in the Monkey, by Captain Lamb, records the results of a series of carefully-conducted experiments carried out by its author at the Research Laboratory, Bombay, together with his observations thereon. The concluding article, by Major Roberts, which is of a very practical character, on the Methods of Sanitation in India with Special Reference to Cantonments, has, as we have already said, been previously noticed. These memoirs are written in a thoroughly scientific spirit and are admirably illustrated, and their production is highly creditable to the Indian Medical Service.

LIBRARY TABLE.

*Physiologie.* Von Dr. P. SCHULTZ. Second edition. Illustrated. Berlin: S. Karger. (British importers: Williams and Norgate, London.) 1901. Pp. 364. Price 7s.—This is exactly the sort of book to fill the critical soul of the reviewer with an agonising sense of his own ineptitude for the task of reviewing. There is nothing to criticise and nothing to commend. Dr. P. Schultz's "Physiologie" presents a dull level of accurate physiological fact. We have searched, we will admit, for some inaccuracy, some *lapsus calami*, some unguarded expression of opinion, which might relieve the dull monotony of its hopeless mediocrity, but for all our pains we have searched in vain. We must, however, express our gratitude to the

<sup>1</sup> THE LANCET, July 6th, 1901, p. 29.

author for providing us in his preface with the **very** cue for which we were racking our brains, so that we might express in the fewest possible words our sentiments on the literary merits of this compendium. In the words of Terasson, this work "would have been much shorter if it had not been so short," and in those of Kant, "much plainer if it had not been so plain." It is not, however, from the standpoint of the British reader or of the British student that the value of this compendium should be estimated, but rather from that of the candidate for the German "Staatsexamen," for whose powers of assimilation no man can be accountable and whose traditional thirst for accurate information may well be satiated in the cup which Dr. Schultz has filled to overflowing. Regarded from this point of view—that is to say, as a compendium of exact physiological information for students preparing for a cut-and-dried examination, in which accuracy is at a premium and independent thought and controversial considerations at a discount—this "Studentenbuch" must be regarded as entirely satisfactory. The contents are divided into 24 chapters, each of which constitutes a complete lesson in itself. The illustrations, though not numerous, are excellent of their kind, while the print is small and very trying to the eyes.

*Operative and Inoperative Tumours of the Urinary Bladder: a Clinical and Operative Study based on 500 Cases.* By E. HURRY FENWICK, F.R.C.S. Eng., Surgeon to the London Hospital, Surgeon and Pathologist to St. Peter's Hospital for Urinary Diseases. London: J. & A. Churchill. 1901. Pp. 124. Price 5s.—The surgery of the bladder owes much to the cystoscope. Before the invention of this instrument it was certainly sometimes possible to form a diagnosis on the nature of a vesical growth, but the diagnosis was frequently difficult and often was erroneous. Our present knowledge of the cystoscope enables us frequently to speak with certainty on the nature of a tumour of the bladder and we are justified in recommending or advising against any operative procedure. Not only does this diagnostic means aid us in deciding what cases are unfit for operation, but by the knowledge gained by cystoscopy we undertake more readily an operation in a suitable case. The use of the cystoscope is widely spread, and it is not always recognised that much familiarity with the instrument is needed before reliance can be placed on what is seen, for it is not merely necessary to see the growth, but it is equally needful to be able to interpret what is seen. As Mr. Fenwick's work is based on 500 cases which he has himself treated it may be worth while to quote the four rules he lays down for the examination of tumours of the bladder. They are as follows: "Rule 1. Always cystoscope, never sound, for symptomless hæmaturia. Rule 2. A gentle rectal examination should be the first step in the inquiry. Rule 3. Dark hæmaturias without clots rarely need any preparatory washing-out for clear cystoscopy; a diuretic often suffices. Rule 4. Always cystoscope and operate, if necessary, at the same sitting if the bladder has to be washed out." The difficulties of cystoscopy are then described. The author divides vesical tumours into (1) the benign villus-covered growth; (2) the malignant villus-covered growth; and (3) the bald malignant growth; and these three forms and their clinical histories are then described. The operative treatment of growths of the bladder is fully given. Mr. Fenwick has operated 135 times with nine deaths. He objects to the use of Petersen's bag, as it is in his opinion not merely useless but liable to produce secondary cystitis by traumatism of the rectal mucous membrane. He prefers to make the opening into the bladder only large enough to admit the forefinger. For accurate work the author thinks highly of the use of a caisson, for by its use only a small opening is necessary, and manipulations are much simpler, and the whole growth can be readily removed. Caissons of different sizes are

employed. The light is obtained from a small head lamp. The book contains almost entirely the methods practised by the author himself and refers but little to other modes of treatment; still, as Mr. Fenwick has devoted much attention to this branch of surgery the work is of great value.

*Treatment of the Insane Then and Now.* By the Rev. HENRY HAWKINS, M.A., late chaplain of Colney Hatch Asylum. London: Society for Promoting Christian Knowledge. 1901.—In this little brochure of 32 pages the late chaplain of Colney Hatch Asylum gives a concise and interesting account of the treatment of lunatics in the eighteenth century when, "after all allowance was made, the management was often superstitious and inhuman," and contrasts it with the more humane and enlightened methods which were introduced in the early decades of the nineteenth century by Pinel, Tuke, and other apostles of humanity and which are uniformly in operation now. Reference is made to the bright and cheerful surroundings in which the lunatic is placed in our modern asylums, to the careful provision for their religious privileges, and to the special royal and naval hospitals for soldiers and sailors suffering from mental derangement. The basis of the compilation is acknowledged as resting on the late Dr. D. Hack Tuke's "History of the Insane in the British Isles," with excerpts from the report of the Commissioners in Lunacy published in 1900. The little work is popularly written and is intended to give the lay mind an outline of the differences between the conditions of lunatics now and a century ago.

*Golden Rules of Hygiene.* By F. J. WALDO, M.D. Cantab., D.P.H., Barrister-at-Law. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1901. Pp. 69. Price 1s.—This is the tenth of the excellent little "Golden Rule" series and the author's name is sufficient to guarantee the practical nature of the notes which it contains. It is written with the idea of collecting together in a succinct form—the little book may easily be carried in the waistcoat pocket—a few salient points that may prove of service in the acquisition of a practical knowledge of hygiene, the subjects treated being air, water, disposal of refuse, food, and infectious diseases. Under the heading of food milk is, of course, included, but we fail to see any reference to butter. Several common epidemic diseases may be caused by contaminated milk, and the author rightly alludes to this fact in his notes of warning; and butter is quite as likely to convey disease as is milk. This fact is too often overlooked.

#### JOURNALS AND MAGAZINES.

The *Medical Magazine* for September is largely occupied by prospectuses of the different London, provincial, Scottish, and Irish medical schools, and various preparatory institutions. Dr. P. Brouardel's articles on the measures adopted by several nations for the Prevention of Consumption are concluded, and Mr. A. G. R. Foulerton writes on the Influence of Secondary Infections in Chronic Pulmonary Phthisis. Mr. Foulerton considers the nature of chronic pulmonary tuberculosis before secondary infection has converted it into one of chronic pulmonary phthisis. Uncomplicated pulmonary tuberculosis is, he admits, very rarely met with in practice, but frequent evidence of its occurrence is given in the post-mortem examinations of persons who have died from other causes. The secondary infecting bacteria are mainly the pyogenic cocci, particularly streptococcus pyogenes. He notes that the bacteria which under normal conditions are most often arrested in the fore part of the nasal passage, are those which are most frequently found infecting pulmonary cavities. Mr. Foulerton believes that the treatment of secondary infections should be the chief object aimed at in the treatment of phthisis. The magazine contains also an abstract of the Wilde lecture on the "Flora of the Human Body," by M. Elie Metchnikoff.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 12, 1901.

## The Treatment of Cancer.

IN a leading article in *THE LANCET* of August 31st last, p. 601, we referred to the address by HIS MAJESTY THE KING to the foreign delegates at the British Congress on Tuberculosis, in which HIS MAJESTY said: "There is still one other terrible disease which has up to now baffled the scientific and medical men of the world, and that is cancer. GOD grant that before long you may be able to find a cure for it or to check its course." Such a wish will be echoed in every quarter of the globe. For the purpose of our present remarks we may take the term "cancer" as synonymous with "carcinoma." At the present time operation is the only means that offers any certain hope of cure and then only under particular circumstances. It is not our intention here, however, to enter into the prospects of a patient suffering from cancer of the breast, for instance, when submitting to operation. Such considerations have been fully discussed by many authors, but the subject of the treatment of cancer is one which has again been recently brought forward in the lay press, and it is important that false ideas on the subject should not be allowed to become prevalent. In order that a rational treatment of cancer may be established it is first essential that its cause and nature must be fully understood; unfortunately this is not yet the case, but many investigators are at work and the clinical material is only too abundant. A somewhat new departure in the method of investigation has recently been instituted, notably at the Middlesex Hospital, where, as is well known, a special wing is devoted to cancer cases—namely, a systematic investigation under the auspices of a committee to whom a report of the work accomplished is regularly submitted. This scheme has manifold advantages over individual work, although the latter should naturally be encouraged as far as possible by means of grants and opportunities for study. In view, moreover, of the many institutions where cases of cancer are admitted we strenuously oppose the proposition which has been made in a lay paper, that a "cancer clinic" should be established; the multiplication of special hospitals for cancer is not desirable. Philanthropic individuals anxious to serve an admirable cause by giving much-needed funds would do a greater service by assisting existing institutions where such investigations are being at present carried out than by seeking to establish fresh ones.

We are forced to admit, then, that the cause and nature of cancer have not yet been definitely made out, but we have every confidence that the labour of present investigators will bear fruit and will pave the way for a rational treatment of the disease. Meanwhile we are strongly of opinion that it is legitimate to give a hearing to all those who have had opportunities of examining cases and

of trying various measures of treatment. Acting on this principle we publish a paper by Mr. JOHN HOLDEN WEBB of Melbourne who claims that he has met with some success by the injection of soap solution, his theory being that the cause of cancer is cholesterine which has been separated "from the living cell," so permitting the "cell-cancer to start." We cannot say that we have been particularly impressed by the cases which he describes. Nevertheless, we do not feel justified in refusing to publish such an article as the one under discussion, as every method which holds out any hope of success should be duly tried. The same remarks apply to the article published in *THE LANCET* of Sept. 28th, p. 845, entitled "The Prospect of Cure in Cancer," by Dr. H. MANDERS, who advocates the employment of electricity in the treatment of cancer and maintains that in currents of high potential and exceeding frequency there is a means, hitherto unknown, of stimulating the vital energy of cells and of enabling them to utilise auxiliary remedies.

The belief that a satisfactory treatment of cancer is possible without recourse to operation, or perhaps we should say in cases where operation is undesirable or impossible either on account of the situation of the disease or its extent, is strengthened by cases which have been recorded in which the malignant disease has spontaneously disappeared. Mr. A. PEARCE GOULD brought a remarkable case of this nature before the Clinical Society of London<sup>1</sup> in which a cancer was removed from the breast of a woman by Dr. W. J. COLLINS in 1885, the nature of the tumour being confirmed by microscopical examination, and further operations being necessary in 1892 and 1894. In 1895 she was admitted into the Middlesex Hospital and was then found to have extensive recurrence of the disease, the glands being largely involved. In the following year, however, practically all signs of the disease had disappeared; no special treatment had been adopted. Cases of this nature are, of course, extremely rare, but they prove that malignant disease may be eradicated.

Another method of treatment which has received much attention is the administration of thyroid colloid; some satisfactory results have been claimed. Removal of the ovaries also has undoubtedly in some cases been productive of good results, Dr. G. E. HERMAN amongst others having recorded some successful cases; and these two methods when combined have been found greatly to relieve malignant conditions, even if a cure has not been effected.

In an address delivered on Oct. 4th before the West London Medico-Chirurgical Society by Mr. ALFRED COOPER (see p. 965) the present treatment of inoperable cancer was fully reviewed and measures were recommended which had been adopted with success. In addition to the performance of oöphorectomy, to which we have already referred, the use of Coley's fluid in cases of inoperable sarcoma was mentioned, and in cases of rodent ulcer and in the superficial malignant ulceration in other parts the Roentgen rays seem to give some hope of improvement. Mr. COOPER is also of opinion that in cases where these methods are declined or are inapplicable the internal administration of celandine is worthy of trial.

The greatest caution is, of course, necessary in considering

<sup>1</sup> Transactions of the Clinical Society of London, vol. xxx., 1897, p. 205.

any mode of treatment that may be advocated. As in the case of all diseases of which the nature is doubtful quack remedies or modes of treatment which have apparently been of benefit in a single case may be counted in dozens, but it is scarcely necessary to point out that for any therapeutic measure to be seriously considered it is absolutely essential that the nature of the growth should be firmly established, if possible by microscopical examination or by the examination of competent observers, and also that a series of cases should be treated, before even a temporary opinion can be arrived at. We say this in explanation of what we maintain above—that all measures which have been found to give relief in cases of cancer should be duly considered and carefully tried. Once more we must protest against attempts to stir up public feeling in the lay papers with regard to what are termed “experiments upon hospital patients.” Such statements are made by persons entirely ignorant not only of the methods adopted by physicians and surgeons attached to hospitals but also of everything connected with medical science. It is useless, however, we fear, to argue with such people or with the editors who allow such communications to appear in their columns, communications which are calculated to injure charitable institutions and to hinder the advance of scientific knowledge.

## The Reorganisation of the Army and Indian Nursing Service.

WE endeavoured to deal last week with the report of Mr. BRODRICK'S Committee on the Reorganisation of the Army Medical Services in a broad, comprehensive spirit. While we stated that some of its recommendations might have either to be developed still further or to be modified and that the effect and working of them must for the time partake of the nature of experiment we nevertheless recognised that the report, as a whole, was framed on bold and generous lines. We assumed that in any case a good deal of freedom of action would within those lines be open for such improvements or modifications of the new scheme as were hereafter found advisable or necessary. One of the grave problems of modern warfare, which the course of events in South Africa has brought out so prominently, is the proper care and nursing of the sick and wounded. It is not surprising, therefore, to find it recommended that the Nursing Service should be specially represented on the Army Medical Advisory Board about to be established and that the matron-in-chief of “Queen Alexandra's Nursing Service” is to be included among its members for that purpose. This naturally brings us to the consideration of the report on the reorganisation of the Army and Indian Nursing Service which was also drawn up by the same Committee that reported on the reorganisation of the Army Medical Services and was issued as a separate document at the same time.

The report on the reorganisation of the Army and Indian Nursing Service consists of eight pages and after a perusal of these we are glad to congratulate the members of the new

Nursing Service on their good fortune in not being called upon to encounter a series of examinations such as beset the path of officers of the Royal Army Medical Corps.

The Committee recommend that there shall be one military nursing service for His Majesty's army in the United Kingdom, India, and the Colonies, to be designated “Queen Alexandra's Imperial Military Nursing Service.” This amalgamated service is to be under the control of a board of which Her Majesty Queen ALEXANDRA is to be requested to assume the presidency. The chairman is to be the Director-General of the Army Medical Service, or an officer nominated by him, and two members of the Army Advisory Board, of whom one shall be a civilian, are to be members of the Nursing Board. The same principle which was so apparent in the report on the reconstitution of the Army Medical Services—namely, that of bringing them into the closest relations with the profession in civil life—is likewise apparent here, for three matrons of large civil hospitals with medical schools are to have a place on the Nursing Board. The other members are to be the matron-in-chief, a representative of the India Office, and two members (to hold office for three years) nominated by Her Majesty the President. The minutes of the proceedings of the Nursing Board are to be laid by the matron-in-chief before the Army Advisory Board and the Secretary of State will, if necessary, decide in cases of divergence of opinion between the two boards. All this sounds a somewhat complicated procedure but it is, we suppose, officially speaking, necessary.

Subject to the general control, then, of the Army Advisory Board the newly-constituted Nursing Board will have a good deal of power and responsibility in advising the Secretary of State upon all matters appertaining to the Army and Indian Nursing Service and its organisation, development, and administration.

There is no need to enter at any length upon those portions of the report defining the functions and duties of the different grades, the conditions of service, and other details regarding pay and allowances, seeing that these are sure to be carefully studied by all directly interested in the subject and that they are very much such as, speaking generally, might have been anticipated. The scheme as it stands on paper seems to have been carefully thought out and to be a promising one, but it is impossible to say until it is practically tried whether it will prove efficient and will realise all that may be hoped from it. Apart from special training, patience, sympathy, gentleness, and devotion are most essential qualities required for successful nursing, and in these respects women excel men. Nursing is a woman's special sphere. If it takes time to make a soldier it takes much longer to make a really good nurse, the value of whose services when obtained is, however, incalculable. We cannot speak too highly of the watchful care, skill, and unselfish devotion displayed by such a stamp of lady nurses in the hospitals of South Africa. We can only hope and believe that the members of the new Nursing Service will have nothing to complain of in regard to the position accorded to their service which under the new *régime* will have a large sphere of influence and independence and, we feel confident, of usefulness also.

## The Reformation of Habitual Drunkards.

THE reclamation of the inebriate, if a difficult, is not quite a hopeless, matter. Experience has proved that in cases where a rudiment of will remains a power of refusal in the presence of temptation can frequently be developed from it. This, in brief, constitutes the psychological justification of what are known as inebriate reformatories. In so far as these institutions can be made to promote successfully this process of will-cultivation in so far will they have secured for themselves a *locus standi* in respect of the work they do. There are, it is true, various economic points to be considered in defining their proper position. At the outset it should be noted that, as stated in our issue of Sept. 28th, p. 862, we do not regard the drunkard as one who is merely the subject of mental disease. Occasionally he may, indeed, become such, but the habit of drunkenness in itself is not insanity. It is the custom with many advocates of temperance to speak as if the captives of self-indulgence were well-nigh hopeless of deliverance and practically rid of personal responsibility. If they were so reform were equally hopeless. It is because we do not agree with this view of the case that we are disposed to look with approval on any rational project for their moral reconstruction.

Since the passing of the Inebriates Act of 1898 a considerable amount of attention has been attracted to the system which provides for this class of people the educational restraint of a reformatory. From the report of the establishment for female inebriates at Farmfield, Surrey, it is possible to form some idea of the plan on which a work of this kind may be carried out and of its future possibilities. The estate of Farmfield was purchased by the London County Council and adapted to its present use at a cost of £19,965. It comprises 374 acres of farm land of moderate quality and provides accommodation for 30 female inmates. A further sum of £20,000, it is stated, has been allotted with a view to the housing on the estate of 80 more women. A plain but not a sparing diet, of course without any intoxicant, and an eight-hours' working-day form the daily rule of life. The usual occupations consist of laundry, dairy, and farm work. The cost of maintenance is not light. Up to the present time it has amounted to £1 9s. 4d. per head per week. The Farmfield colony has been less than a year in existence, and none of the inmates have as yet been allowed to leave on licence. Consequently, it is impossible to gauge the measure of success achieved in it. The opinion appears to prevail, however, that detention for at least a year, and preferably for a longer period, is necessary before anything approaching a reformation of character can be looked for. It is, indeed, impossible to speak with any confidence on this subject. The whole reformatory scheme is in its experimental stage. For this reason it seems advisable that the system should not be too readily or as yet too widely adopted. It must be borne in mind that some time must elapse before it is possible to tell how far the after-life of inmates has been able to follow the course to which it was introduced in the reformatory.

There is, moreover, as we have said, an economic as well as

a moral side to this subject. County and borough councils are certainly not justified in going to any length in order to carry out even a work of reclamation. Some regard must be had to the social position of inmates in reformatories. When the income of the inebriate or of his relatives can procure his admission into one of the numerous "retreats" where payment is required it is not to be tolerated that the ratepayers should be taxed for his maintenance. Nor in the case of the pauper inmate should provision be made for idleness. It is no less essential to the well-being of the drunkard than fair to his temperate neighbours that while under care he should work for his living and earn it. Unless this rule be carried into practice we cannot see what justification there is for a reformatory, since it must not only prove a drag on the public purse, but must surrender a material part of its reforming method. A suggestion has been made that the less tractable inmates of the ordinary certified inebriate reformatories such as that at Farmfield should be taken in hand by the State which is expected to provide a special form of reformatory for their reception. It is true that powers are granted under the Act for the establishment of State reformatories for criminal drunkards, but we are tempted to inquire whether the place which they are intended to fill could not be found within the walls of prisons already existing. There it should not be difficult to exclude alcohol while promoting habits of industry. It seems somewhat superfluous that another place of restraint should be provided for the intractable inmates of certified inebriate reformatories.

## Annotations.

"No quid nimis."

### MEDICAL OFFICERS OF HEALTH AND DIAGNOSIS.

A CORRESPONDENCE involving a point of considerable interest to medical officers of health and to medical practitioners generally has recently taken place between Dr. David Roxburgh of Bryanston-street, W., and Mr. A. Wynter Blyth, medical officer of health of St. Marylebone, and has been made public by the former gentleman.<sup>1</sup> Stated briefly the question arose from a case of small-pox with regard to which Dr. Roxburgh, who was attending the patient, felt doubtful and which he accordingly did not notify as such, but with regard to which he informed the medical officer of health of the district in which it occurred. There appears to be some question between Dr. Roxburgh and the Public Health Committee of St. Marylebone as to the time which elapsed before the case was finally diagnosed and removed, but with respect to what actually took place Mr. Blyth writes as follows: "Immediately on receipt of your letter I telephoned to Dr. Greenwood, and he saw the case between 11 and 12 midday, and a second time in the evening," and from this passage it is apparent that he does not limit his duties in practice as he would seem to limit them in theory from the next paragraph in his letter. He there writes, "I am always pleased to assist my medical *confères*, but you must understand that the diagnosis of cases is no part of the duty of a medical officer of health; the responsibility of diagnosis rests with the medical attendant entirely; after

<sup>1</sup> The Times, Oct. 8th, 1901.

the diagnosis is made and the case notified the duties of the sanitary officers commence." Taken literally, and acted upon, this statement of the position would in many cases lead to disastrous consequences, and would probably bring the medical officer of health into serious collision with the local authority employing him. The medical attendant of a sick person must not shirk his responsibilities; he must notify in the case of certain specified diseases, if in his opinion his patient is suffering from one of them. Should he fail to do so he is liable to prosecution, and for this very reason, if he writes to the medical officer of health during an epidemic of small-pox and gives information to that official of a case with regard to which he declines to advance a definite opinion, he may almost be assumed to do so with the knowledge of his position and of the danger of shirking responsibility should such responsibility really rest upon him. It is, however, perfectly well known that errors of diagnosis may be made, and, in fact, have been made, in cases of small-pox, and that a wrong decision, resulting in a case of small-pox escaping notification and the measures consequent upon notification, may be a very serious matter for the community at large. Mr. Wynter Blyth's view, as expressed in his own letter without qualification, is that the diagnosis of cases is no part of the duty of a medical officer of health. As we have suggested, he may depart from it in practice, but, taken merely as an academic statement of principle, it will hardly bear investigation. He is not, of course, to be regarded as a consultant who may be called in when any practitioner is in doubt; but he, for example, would not, either in theory or practice, be justified in sending to a small-pox hospital and otherwise dealing with a case notified as small-pox if he felt sure that the medical man who had certified it had done so in error, while the course he would thus take would be the result of his own diagnosis. Again, it is the duty of a medical officer of health, beyond all question, where he has an admitted case of small-pox to trace its origin and to ascertain, if possible, whether other persons may have been infected by it. If in the course of such an investigation he finds that the patient has been in frequent contact with a person who in the opinion of a medical practitioner is at the moment suffering from chicken-pox, can the medical officer of health in such a case say that diagnosis forms no part of his duties or that they only begin after the diagnosis is made by someone else and the disease notified? It is not easy to define where the duties of a medical officer of health either begin or end at any time, and during the occurrence of small-pox in his district their limits may be said to extend themselves. They include the searching out and, if possible, the stamping out of the disease in his district, and they involve coöperation with everyone who will assist in the task in his district or elsewhere. If a medical practitioner informs a medical officer of health that a case under his treatment may be small-pox and declines to certify it as such he may be evading a duty which the law imposes on him, and whether he be doing so or not is a question of fact, though not perhaps an easy one, which a magistrate may be called upon to decide. He may, on the other hand, be giving the earliest possible information as to a case in which early information is of the utmost importance and of which early information should beyond all question be given, even if it does not take the form of a certificate. That Dr. Roxburgh could not be blamed for not giving a certificate when he made his first communication seems clear from the fact that after this Dr. Greenwood saw the patient twice with an interval of several hours between his visits before she was removed. We have commented on Mr. Wynter Blyth's letter, not because we have any fault to find with his conduct, but because the second passage which we quote from his letter seems to suggest the view that Dr. Roxburgh would have done better to have waited until he

was prepared to enunciate a definite opinion embodied in a certificate, and that the St. Marylebone Borough Council, acting through their medical officer of health, would have been morally or legally justified in not acting until such a certificate was given. Neither of these views could be upheld for one moment, and the occasion is one for coöperation rather than for discussion.

#### THE RECONSTITUTION OF THE ROYAL ARMY MEDICAL CORPS.

It may be well to make it known to would-be candidates for admission to the Royal Army Medical Corps that the reconstitution scheme drawn up by Mr. Brodrick's Committee, the full text of which was published in our issue of Oct. 5th, p. 929, is *only a scheme*. Before it can be acted upon or taken advantage of it will have to appear as a Royal Warrant. Before this happens the outline scheme as published may be modified or amended in various ways. It is therefore quite useless for anyone to write or to call at the office of the Army Medical Department for information concerning the date of the next examination or any other points in the scheme, for nothing more is known than has been already published, and any letters asking for further information are merely a waste of time on the part both of those who write and of those who receive them.

#### DIFFERENTIAL DIAGNOSIS BETWEEN SMALL-POX AND CHICKEN-POX.

In another column we publish a letter from a correspondent drawing attention to the fact that the vesicles in chicken-pox are unilocular, whilst in small-pox they are multilocular, so affording a valuable differential test between the two diseases. As has been shown in the present outbreak of small-pox the diagnosis between that disease and chicken-pox is of considerable difficulty and, needless to say, an error may give rise to grave results, not only to the individual affected, but to the community at large. There are other differences between the two of which we may remind our readers, more particularly as the younger generations of practitioners have not had many opportunities of observing cases of small-pox. The initial symptoms are not so marked in chicken-pox—indeed, they may be entirely absent, whilst in small-pox the constitutional symptoms appear early and there is high fever. It is, however, to the eruption that most attention is naturally directed. In chicken-pox it is most abundant on the trunk and is less on the face and extremities. It is discrete and may appear in one crop or in successive crops, during a period of from one to five or more days. In small-pox the eruption is most abundant on the face, arms, and legs; moreover, there is a characteristic fall of temperature after the appearance of the rash. In chicken-pox the eruption is at first macular or papular, but becomes vesicular within a few hours. The vesicles vary in shape according to the part of the body on which they are situated, being oval on the chest, abdomen, and back, circular on the scalp, and irregularly round on the face, whilst on the arms and thighs they are mostly circular. The vesicles likewise vary in size on the various regions. They are clear, bright, and shiny and filled with a clear fluid. In small-pox the eruption is not fully vesicular within from six to 12 hours of its appearance, and the vesicles when formed are not oval. Previous vaccination frequently changes the characteristics of the small-pox eruption. Dr. J. MacCombie, writing in Professor Clifford Allbutt's "System of Medicine," also points out that on the extremities the similarity of the vesicles of chicken-pox to those of modified small-pox usually increases in direct ratio to the distance from the trunk. In many cases of chicken-pox the vesicles on the forearms, legs, backs of the hands, and back and dorsum of the foot

are round and hard, small in size, not unlike the eruption of modified small-pox, and if only the eruption on the forearms, hands, legs, and feet be observed it would be impossible in more than half the number of cases to say whether the disease was chicken-pox or small-pox. But all cases of small-pox present typical vesicles on either the abdomen, chest, back, thighs, or arms. Especial regard must therefore be had to the distribution of the rash, and especially to the fact that in chicken-pox some of the vesicles at least have reached their full development within one day from the appearance of the papule, while in small-pox the vesicles are not fully developed until five days after the appearance of the eruption.

#### TEMPERED CAPTIVITY.

MR. EDMUND SELOUS was moved to considerable indignation in the *Saturday Review* some months since by the condition of various animals in the Zoological Gardens; his emotions still seek a new outlet in a partial reprint of those articles which has been issued with the assistance of the "Humanitarian League." The writer of this pamphlet reads into the animal mind purely human feelings, an error which is exceedingly widespread. The study of animal psychology, as has been pointed out again and again, is apt to be most seriously impeded by this commonly accepted anthropomorphism. It is quite inaccurate to compare the sufferings of a man with those of a quadruped; our miseries, even purely physical pains and pangs, are so interwoven with experience, reflection, and brain processes generally that they are entirely changed in character. In altogether waiving discussion upon this very important point—indeed, in practically asserting an entire community of feelings and emotions between the lower animals and ourselves—Mr. Selous commits himself to extremely uncertain ground upon which to base an indictment of the actions and inaction of the Zoological Society. Besides, judged by such tests as we can apply, for example, by healthy appearance, alertness of demeanour, and by appetite and longevity, Mr. Selous's sympathies require revision. A parrot that lived for 54 years, a polar bear, a crane, a pelican, and a condor that survived among these alleged miseries for periods varying from 30 to 40 years, and plenty of other instances to which Mr. Selous can gain access, are not in absolute harmony with his views. Mr. Selous deprecates "an inaccuracy, however slight," as likely to damage his case. Properly impressed by this desire to avoid misstatements Mr. Selous would have done better to consult someone with adequate zoological knowledge, and others acquainted with the difficulties of, and problems connected with, keeping live animals before printing for a second time "The Old Zoo and the New." He should also have ascertained the precise circumstances of some of the creatures to which he refers. The swan allowed with "cruel absurdity" a minute basin to wash in was temporarily deposited in such a place. The great bustard was destroyed. The "jackals, large wolves, and wild dogs" are not limited to "brick yards about the size of a kitchen area"; they have in addition a considerable and dark den behind. When Mr. Selous observes of the wild cat that it utters a sound "between a moan and a snarl—a striking sound eloquent of fierce suffering"—he is a pure inventor of feline language. The eagle is thought by Mr. Selous and by the inexpert public generally to be mainly occupied in soaring and generally admiring the landscape. The eagle does not soar so much except to look for prey. If Mr. Selous knew much of the habits of monkeys he would not suggest a profusion of tropical trees for them to climb among. There would not be a leaf left by these mischievous creatures in a few hours. The "aerial shrubbery" desired for the chimpanzees and orangs would not long be in existence. Mr. Selous thinks

that the "poor apes," which he elsewhere "amusingly" terms "bosky Pucks," should be given opportunities for retirement. Tamed animals do not shun man. Eagles, vultures, kites, and owls, which Mr. Selous would exclude from his ideal "Zoo," live long in captivity and breed. Seals and penguins in Mr. Selous's ideal "Zoo" are to "get on very well together." Yes! The agreement would be thorough but gastronomic. The penguins would end the day within the seals. Otherwise there is no fault to be found with Mr. Selous's "Garden of Delight." We should be as glad as he to see it. But the Zoological Society must first of all add to its income a good many more thousands of pounds. Then the writer of the pamphlet before us would probably moderate his curious objection to the large number of species exhibited by the society and would cheerfully cry "Let them all come" (recollecting, though, we will hope, that he is not quoting Mr. Pickwick accurately, as he thinks he is) with the rest of us. The best method of attaining this desirable end—for Mr. Selous has no primary objection to captive animals—would be to encourage the public to visit the gardens instead of dissuading them by appealing to the most ignorant kind of sentimentalism, and to temper his criticisms with a greater amount of knowledge acquired on the spot—by admitting, for example, that while during the last few years large structural changes for the better have been effected in the erection of new houses there is every prospect of continued advance as far as the society's income will allow.

#### THE SOUTHWARK BOROUGH COUNCIL AND ITS PUBLIC ANALYSTS.

AT a meeting of the Southwark Borough Council held on Oct. 2nd at the Southwark Town-hall the Public Health and Sanitary Committee reported that they had had under their consideration the question regarding the public analysts at present holding office in the borough. It appeared that Dr. John Muter was appointed by the late Newington Vestry and the St. George's Vestry in 1872 and Dr. Richard Bodmer by the late St. Saviour's Board of Works in 1890. Dr. Muter was paid at the rate of 10s. 6d. per sample and Dr. Bodmer at a salary of £105 per annum for a maximum of 200 samples. The fees received by Dr. Muter alone during the quarter ending June last were £250 9s. 6d., and the amount was more likely to increase than to decrease. The committee had every reason to believe that the council could obtain the services of a fully-qualified public analyst to devote the whole of his time to the work of the council at a maximum salary of £500 per annum. The cost of fitting up and maintaining a laboratory and providing the necessary apparatus and materials, together with the services of a capable assistant, was estimated not to exceed £300 per annum, and having also in view the time which would be saved by the inspector in carrying samples to the analyst the committee were unanimously of opinion that a considerable saving would be effected by the appointment of one public analyst. Assuming that the Treasury should be of opinion that Dr. Muter was entitled to any compensation for loss of office the amount of pension based on the Treasury scale, without taking into consideration any deduction on account of apparatus and chemicals necessary to enable him to earn his fees, would amount to between £140 and £160. With regard to Dr. Bodmer, the amount of compensation would not exceed £25. They therefore recommended that the council should abolish the two offices and should appoint one public analyst to devote the whole of his time to the service of the council at a commencing salary of £400, rising by annual increments of £25 to a maximum of £500, the council to provide a laboratory, apparatus, and all necessary assistance. This was agreed to by the council. The council are well advised in adopting the recommendation of the committee. The appointment of public analyst should be

subject to the same conditions as that of medical officer of health, though always held by a different individual. The maximum salary might be £600 and not £500.

#### ST. THOMAS'S HOSPITAL: THE CHESELDEN LODGE OF FREEMASONS.

A WARRANT has been granted by the M.W. Grand Master for the formation of a Lodge to be called "the Cheselden Lodge," No. 2870, and the ceremony of consecration will be performed on Monday, Nov. 4th, at the Governors' Hall in St. Thomas's Hospital in the presence of the M.W. Grand Master H.R.H. the Duke of Connaught and Strathearn, K.G. (President of St. Thomas's Hospital), who will himself undertake a most important portion of the ceremony. The officers named in the warrant are W. Bro. Thomas Wakley, jun., L.R.C.P. Lond., as Worshipful Master, Bro. H. H. Clutton, F.R.C.S. Eng., as Senior Warden, and W. Bro. G. J. Crawford Thomson, M.D. Durh., as Junior Warden. It will be noticed that the name chosen for the lodge is that of the great anatomist and surgeon of St. Thomas's Hospital who introduced the operation for lateral lithotomy. Freemasons connected with the hospital who desire further particulars concerning the lodge can obtain information by applying to Bro. C. R. Box, M.D., 2, Devonshire-place, Portland-place, W.

#### MALARIA IN HONG-KONG.

WE have received a copy of a clinical report on malaria as seen in the Government Civil Hospital at Hong-Kong, compiled by Mr. J. Bell, acting principal civil medical officer, and Lieutenant G. Stewart, I.M.S., acting assistant superintendent. The report was laid before the Legislative Council by command of His Excellency the Governor. The blood of all patients with fever was examined and not only of those patients obviously suffering from malaria. Some interesting observations were the result of this investigation. Hong-Kong and most tropical countries are looked upon as being very prejudicial to the cure of tubercle. Amongst the Chinese in Hong-Kong the high mortality is put down to overcrowding and insanitary surroundings, but this cannot apply to Europeans and Indians, who form the bulk of the patients in the hospital and who suffer quite as much as the natives. Of 17 cases in which the blood was examined 15 were found to be complicated with malaria, and Mr. Bell and Lieutenant Stewart believe, and probably rightly so, that the malarial combination accounts in a great measure for the rapidity with which the disease advances. It is generally considered that malaria does not produce suppuration in the liver, but in two cases of hepatic abscess the characteristic blood-changes of malaria were demonstrated. Two cases of appendicitis were examined and both showed malaria. The combination of malaria with dysentery is, of course, very common. Out of 37 cases examined 35 showed malarial parasites. In the treatment of these cases quinine was found most useful in addition to salines and ipecacuanha; indeed, the writers of the report remark: "We would almost say that, if a case of acute dysentery does not improve in 48 hours under the latter treatment [salines and ipecacuanha] it is combined with malaria and requires quinine either by mouth or by enema." The combination of malaria with typhoid fever is most interesting to tropical practitioners. The diagnosis frequently presents many difficulties. Mr. Bell and Lieutenant Stewart examined 10 cases which had been seen by other practitioners several times, all of whom confirmed the diagnosis of typhoid fever. All the cases showed in the blood evidences of malaria. The effect of the complication on the chart was various. In some cases for several days the temperature intermitted regularly and markedly until, apparently, the malarial influence ceased to exert itself and

the typhoid element became predominant; in others, however, notwithstanding quinine, there was no intermission, and the chart throughout was more characteristic of typhoid fever. The writers state that they did not find much assistance from Vidal's reaction. The conclusion they arrive at is that in a case where the diagnosis is doubtful, if after thorough treatment by quinine for 10 days the temperature does not fall, in the absence of any symptom to account for the continued rise the case is in all probability one of typhoid fever. Mr. Bell and Lieutenant Stewart further remark that typhoid fever is considered to be a more fatal disease in the tropics than in temperate climates, and they suggest as an explanation that the malarial element which is so frequently present may account for the high rate of mortality. There are other matters in the report that we might draw attention to: we have perused it with much interest and we trust that a similar report for another half-year will be forthcoming.

#### A CASE OF FUNGUS POISONING.

THE *Newcastle Daily Journal* of Sept. 27th describes a case in which three young children, named Mason, Dodds, and Borthwick, picked some poisonous fungi in a field and were very soon taken ill. The report proceeds: "The children had to be carried to their homes and Dr. Story was promptly summoned from Catchgate. He applied the stomach-pump and various emetics. Dodds was the worst sufferer, and the doctor had to inject quicksilver which caused her to vomit a quantity of dark clotted blood. The children were yesterday reported to be out of danger." Being curious as to the reported injection of quicksilver we wrote to Dr. Story who kindly supplied us with the following real details of the case. "The children had eaten toadstools while out picking mushrooms. They came home at 4 p.m. and the child Dodds (the only bad case) went to the shop of a relative situated some yards from home, Dodds's mother being in the shop. Told to go home, the child stood before her mother twitching and grinning. The mother took her to the back of the house where she could see her own door and called her husband. He took the smaller child and beckoned the other to follow. This she failed to do and stood grinning. A niece picked her up, saying, 'There is something the matter with this child; she only grins and can't speak.' The smaller child then said that they had been eating mushrooms. When I arrived the child had been given castor-oil as well as mustard-and-water. The parents had also tickled the back of the throat and tried in every way to get the child to vomit but without success. I injected one-twentieth of a grain of hydrochlorate of apomorphine and in three minutes the child vomited a saucerful of toadstools. Put to bed she slept soundly for several hours." The reporter's interesting "quicksilver and clotted blood" must give way, therefore, to Dr. Story's timely apomorphine and consequent "saucerful of toadstools." Dr. Story's account of the symptoms, if they were correctly reported to him, shows a somewhat unusual effect of what was presumably one of the common poisonous fungi, probably agaricus. It is to be noticed that he does not himself mention seeing any twitching or grinning on the part of the child Dodds. Taken, however, in conjunction with the reported inability to speak, these symptoms may very probably have been present, the child showing early that nervous upset which sometimes precedes and sometimes follows the alimentary disturbances caused by poisonous fungi. In this case, as in most, the symptoms began early. It is only occasionally that they are postponed for 24 or more hours. When nervous symptoms predominate they do not often take the form which they apparently assumed in this instance. More commonly if there are convulsions of any kind they are more general than the "twitching and grinning."

which are probably to be interpreted as a limited convulsive seizure. In a child such symptoms following poisonous ingestion rather suggest analogy with tetany in association with gastric disorder. The nervous symptoms caused by poisonous fungi are not always of a paroxysmal kind. In the case of *Amanita muscaria* a pleasing intoxication is produced, followed by stupor. This is the fungus which has yielded an alkaloid, muscarin, and the active principle of which is excreted in the urine. Among the natives of Kamschatka it is a practice for one to drink another's urine after having eaten of these fungi for the sake of its pleasantly intoxicating properties. Oliver Goldsmith, in his "Letters of a Citizen of the World," speaks of a tribe amongst whom a similar practice prevailed, but in their case a man having eaten of the fungus proceeded to drink his own urine.

#### THE NEW ENTRIES AT THE MEDICAL SCHOOLS.

FROM information which we have received through the courtesy of the deans of some of the metropolitan medical schools it would appear that there may possibly be a falling off in the number of new entries for the full course of medical study. In one case there is a slight increase in students entered for special courses and in another the number of students "entered for partial study, especially in anatomy and physiology, is unprecedentedly large." It is, of course, too soon after the commencement of the winter session to give any precise figures, but this we hope to do as soon as the entries are completed.

#### THE INCIDENCE OF EXPENSE IN ILLNESS.

AN action arising out of a case of typhoid fever was recently heard in the Birmingham County Court in which the plaintiff, a pawnbroker, sued the defendant, a school-mistress. The defendant had visited the plaintiff some years ago, bringing with her a servant who was distantly related to both parties. In the plaintiff's house the defendant's servant developed typhoid fever and was kept there until she was well. The defendant paid the medical man who attended the case, but denied any liability to pay for anything beyond this, and the plaintiff, who had taken in the servant's mother who came to nurse her, bought stimulants ordered for the patient and incurred the outlay incidental to disinfection, now sued for repayment. There was evidence corroborating that of the plaintiff, to the effect that the defendant had undertaken to be responsible for the expenses incurred beyond the medical attendance and the case was finally settled by the defendant making a payment the amount of which was not stated in court. It is not easy to define in a few words the precise legal position of the parties in such a case, but the master of a servant would hardly in such circumstances refuse to compensate his host if asked to do so, and as a matter of justice few will deny that he ought to be made to do so should he refuse. Beyond this, a guest, we should say, is not bound to pay for disinfecting his host's house after the servant of the guest has been laid up in it with an infectious illness, nor is he bound to pay for the board and lodging supplied to his servant as long as his invitation holds good. In the case, however, of a long illness it is almost inevitable that some discussion should take place between host and guest and that some undertaking should be given as to what is to happen eventually if they are in such a financial position that the expenditure involved is a matter of any importance to them, and we have little doubt that such a discussion did, in fact, take place in the case referred to. In the almost inconceivable case of a guest then and there disclaiming all future liability for his servant the host could, we imagine, terminate the visit, with

the result that the guest would be liable to pay for the keep of his helpless servant to the same extent that he would be were the servant lying in his master's house. He could possibly give his servant a month's notice, although humanity would forbid such a step, but would not be entitled to discharge him. Humanity, as a rule, without appeal to the letter of the law settles the course that masters and mistresses adopt when their servants are afflicted with serious illness.

#### SMALL-POX IN LONDON.

IN THE LANCET of Sept. 21st, p. 826, we mentioned that the Rev. Richard Wilson, curate of St. Augustine's, Stepney, was actively encouraging vaccination among hop-pickers in Kent and had proved his sincerity by being himself revaccinated at a village frequented by hop-pickers. Another London clergyman has taken the same method of showing confidence in the protection thus afforded. The Rev. W. D. Sweeting, vicar of Holy Trinity, Rotherhithe, and the other managers of the National Schools in Rotherhithe, had the schools visited by the public vaccinator on Oct. 1st, when the vicar was first revaccinated in presence of the boys, and then 29 boys were vaccinated or revaccinated. The Council of Almoners of Christ's Hospital have decided, in view of the present outbreak of small-pox in London, that all boys in that school who have not been vaccinated or revaccinated within the last seven years shall be forthwith revaccinated with calf lymph by the medical officer. The question of the condition as to vaccination of children attending board schools continues to receive much attention. At a meeting of the Hackney Board of Guardians held on Oct. 2nd, for the purpose of considering a circular letter from the Local Government Board with reference to the spread of small-pox, the clerk said that it was no part of the duty of the vaccination officers to visit board schools and after some discussion the matter was adjourned *sine die*. At a meeting of the Southwark Borough Council held on Oct. 2nd Mr. G. Millson, the medical officer advised that the London School Board should be asked to grant permission for the vaccination officers to visit the schools in the borough and to examine the children, and it was agreed that the matter should be discussed in committee. As already mentioned in THE LANCET of Sept. 28th, p. 859, the School Board for London have announced that facilities will be given to the public vaccination officers, on the application of the proper local authority, to examine the children in the schools with a view to advising the parents to allow their children to be vaccinated, provided that the parents in each case raise no objection to such examination being made. At a meeting of the School Board held on Oct. 3rd a letter from the Local Government Board was read expressing the opinion that it would have been more satisfactory if the school board had not empowered parents to refuse to have their children examined. The Mile-end guardians have declined to take action in regard to a letter from the Local Government Board pointing out the steps requisite to be taken during the prevalence of small-pox. The epidemic extension of small-pox coincidently with the usual seasonal prevalence of scarlet fever and diphtheria threatens to require all the accommodation available in the metropolitan infectious hospitals. With the view of reducing pressure the authorities of the Metropolitan Hospital have offered to the Asylums Board the use of two wards, containing 24 and 12 beds respectively, for enteric fever cases for a period of four months certain, an offer which has been accepted. The Asylums Board have decided to inclose a cemetery at Joyce Green for the interment of patients who have died from small-pox. On Tuesday, Oct. 8th, there were 171 patients in the metropolitan small-pox hospital ships and the shelters on shore; 51 new cases were

admitted to these hospitals, and three deaths were registered in London during the week ended on Oct. 5th. As is well known, mild cases of modified small-pox are sometimes supposed to be varicella (chicken-pox). With the view of meeting this difficulty the Corporation of London, as the sanitary authority of the Port of London, have given notice that the provisions of the Public Health (London) Act, 1891, with respect to infectious diseases shall apply in the port to chicken-pox from Oct. 25th until the close of the year. The St. Pancras Borough Council have also made chicken-pox a notifiable disease for six months, beginning from Oct. 12th.

#### MEDICAL OFFICERS IN THE HIGHLANDS AND ISLANDS.

THE *Glasgow Herald* of Oct. 4th contains the following advertisement:—

**Medical Officer and Public Vaccinator wanted** for the PARISH of STRATH, to take up duty not later than 19th December, 1901. The salary as Medical Officer and Public Vaccinator to be at the rate of £110 per annum. Other appointments may be made. There is a private practice in a population of about 2200. Gaelic a recommendation.—Further particulars can be had from Clerk to the Parish Council, Broadford, Skye, and applications to be lodged with the Chairman, Kilbride House, Broadford, Skye, not later than 23rd October, 1901.

The parish of Strath is extensive in point of area and has a population of about 2200. We learn that the "private practice" is of little value, while "the other appointments" are of little more than nominal value. We can only warn intending applicants to make very sure of three things—fixity of tenure, a free annual holiday, and an adequate salary. We do not consider £110 adequate.

#### THE LONDON HOSPITAL LODGE OF FREEMASONS.

THE London Hospital Lodge of Freemasons, No. 2845, was consecrated on Wednesday, Oct. 2nd, at the Hotel Cecil, Strand, London, by the Grand Secretary, V.W. Bro. Edward Letchworth, F.S.A., P.G.D. The occasion was in every way a notable one, a very large number of Freemasons connected medically or otherwise with hospitals being present. In the ceremony of consecration the Grand Secretary was assisted by the following Grand Officers: W. Bro. Clement Godson, M.D., P.G.D. (as S.W.), W. Bro. Alfred Cooper, F.R.C.S., P.G.D. (as J.W.), Rev. Sir Borrodale Savory, Bart. (Grand Chaplain), V.W. Bro. Frank Richardson, P.G.D. (as Director of Ceremonies), and W. Bro. H. W. Kiallmark, M.R.C.S., P.G.D. (as I.G.). The following is a list of the officers appointed: W. Bro. A. Ernest Sansom, M.D., F.R.C.P., Worshipful Master; Bro. Frederick Eve, F.R.C.S., Senior Warden; Bro. F. J. Smith, M.D., F.R.C.P., Junior Warden; Bro. T. Gilbert Smith, M.D., S.D.; Bro. R. J. Probyn-Williams, M.D., J.D.; Bro. Percy Furnivall, F.R.C.S., I.G.; Bro. T. H. Openshaw, F.R.C.S., Secretary; Bro. S. L. Martin, Treasurer; Bro. G. Schorstein, M.D., Steward; and Bro. G. F. Rogers, M.D., Director of Ceremonies. The founders of the lodge subsequently entertained the consecrating officers and their numerous other guests at a banquet. The Worshipful Master, in replying to the toast of his health, observed that the key-word of this lodge was Heartiness. The work of the senior well-wishers of the hospital in the forming of the lodge was rendered with the heartiest zeal, and the willing response of the juniors showed that a pressing want was supplied. The coöperation of the most representative Freemasons was accorded in a most generous and hearty manner. He desired to express his especial obligations to Bro. T. H. Openshaw, C.M.G., who was secretary of the lodge, and to Bro. Probyn-Williams, who had taken early steps with much energy in the severe work attending the formation of the lodge; but one and all worked heartily. The London Hospital is the fifth of the great metropolitan medical charities to attach to itself a masonic lodge, its predecessors being St. Bartholomew's (Raheere), St. Mary's

(Sancta Maria), Middlesex (Middlesex Hospital), and Charing Cross (Chère Reine), whilst, as announced in another column, St. Thomas's will shortly add to the list a lodge to be called the Cheselden. The West London Hospital also has a lodge named the Cavendish, and we must by no means omit to mention the Æsculapius, which is not a hospital but a purely medical lodge and, we understand, enjoys much success. We wish the London Hospital Lodge a prosperous and useful career. The first Worshipful Master, Dr. Sansom, a well-known and esteemed member of our profession, is equally well known and esteemed in the masonic world, and under his experienced guidance the lodge starts with the best of auspices.

#### THE RÔLE OF SYPHILIS, ALCOHOLISM, AND UNHEALTHY OCCUPATIONS OF THE PARENTS IN THE ETIOLOGY OF IDIOCY.

In a brief but important communication to the French Congress of Alienists and Neurologists made by Dr. Bourneville of the Bicêtre, Paris, and published in the *Revue Neurologique* of August 30th, it is stated that out of a total of 2072 boys suffering from chronic diseases of the nervous system (idiocy, imbecility, epilepsy, and various paralyses) the presence of hereditary syphilis was ascertained in 20 cases, or about 1 per cent. Among 482 girls there were only two cases of hereditary syphilis, or 0.2 per cent. Alcoholism, on the other hand, was a more prolific cause of disease, its presence being traced in over 40 per cent. of the cases. Thus of the total number of patients, both male and female, the family histories showed that in 36.5 per cent. of the cases alcoholic intemperance was present in the father and in 3.0 per cent. in the mother, while in the rest—viz., 1.5 per cent.—it was found in both parents. Among the unhealthy occupations in which the parents of the patients were engaged were the making of phosphorus matches, working in copper and in mercury, and especially the manufacture of white lead.

#### THE MEMORIAL TO SIR THOMAS BROWNE.

For some little time past a scheme has been on foot for the erection of a memorial to that bright ornament of the medical profession, Sir Thomas Browne. The memorial is to take the form of a statue to be erected in Browne's native city of Norwich, and in our issue of March 2nd, 1901, p. 649, we were enabled to announce that a sum of over £600 had already been received towards the expense of the statue. A correspondent now informs us that he has heard that a sum of between £300 and £400 is still wanting. The Royal College of Physicians of London have voted a subscription, but comparatively few of the members of the medical profession have individually supported the movement. This is not as it should be. In our issue of Jan. 12th, 1901, p. 113, we commented upon the action of Colchester, or rather the medical men of Colchester, in erecting a memorial to the memory of William Gilbert who laid the foundations of the science of magneto-electricity. We there pointed out how few memorials of our great men of science were to be found in this country and urged the medical profession as well as other members of the body politic to follow the example set by the medical profession of Colchester. Sir Thomas Browne comes perhaps in a different category to Gilbert, Sydenham, or Harvey. He did no great scientific work, so far as we know, but it is on record that "he was much resorted to for his skill in physic." He lived a quiet unostentatious life and did good by stealth. He was not free from the faults of his age and believed in the burning of witches. But despite this he was not unduly credulous, as his treatise "Pseudodoxia Epidemica" very well shows. In an age when religious

differences were very bitter he maintained a most tolerant mind. He was an earnest Churchman, a good friend, and one always ready to succour his neighbour, while by his writings he has enriched English literature with treasures which will be a possession for ever. Certain passages in the "Hydriotaphia," in the "Letter to a Friend," and in the "Religio Medici" have a music and majesty of diction which can be perhaps only paralleled by portions of the Prayer-book or the Authorised Version of the Bible. There are, we know only too well, many calls on our purses. Obligatory claims such as rates and taxes are more pressing than ever and coincidentally many charities are suffering. But the sum required is not large. If every practitioner in England alone were to give but 1s. respectively twice the money required would be raised. It is not too much to hope that many of us could afford 10 or even 20 times 1s. Subscriptions may be sent to Mr. Frederic R. Eaton, King-street House, Upper King-street, Norwich, who is the honorary secretary of the memorial fund.

#### NEW LIVERPOOL ANTI-MALARIA CAMPAIGN ON THE GOLD COAST.

OWING to the generosity of a philanthropic merchant who desires to keep his name private, and to promises of assistance made to Major Ronald Ross by His Excellency Major Nathan, C.M.S., Governor of the Gold Coast, the Liverpool School of Tropical Medicine is immediately sending out Dr. Charles Balfour Stewart to undertake a campaign against malaria in that colony. He will proceed first to Sierra Leone in order to study the methods now being employed there with such success by Dr. Logan Taylor, to which we refer in another column, and will first attack the disease in the town of Cape Coast Castle, where, according to many reports, there is at present a considerable mortality among Europeans. Dr. Balfour Stewart will have full charge, under Major Ross's general direction, of the operations on the Gold Coast, and will probably be soon furnished with assistants. The line he will no doubt adopt will be that of drainage of the ground and clearing out broken vessels of water from the houses by means of large gangs of workmen, as has been done in Freetown. He is engaged for one year, but will probably remain as long as his services are needed for the great work which he is called upon to conduct in this rising and already important colony. He will shortly be able to pay special attention to the gold-mines, but his movements will be largely determined by the wishes of the Governor. Anti-malaria operations will thus shortly be in full swing all down the coast from the Gambia to Lagos—three of the colonies being dealt with by the Liverpool School of Tropical Medicine.

#### THE FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

THIS Congress was held at Turin from Sept. 17th to the 21st. The attendance was large—more than double that of any of the previous meetings. The inaugural address was delivered to an audience of more than 200 members by the President, Professor Angelo Mosso of Turin, who proposed that the Congress as its first duty should appoint Sir Michael Foster of Cambridge honorary life president in recognition of the important share which he had taken in the foundation of International Congresses of Physiology. This proposal was, as we have already recorded, carried unanimously, as was likewise Professor Kronecker's that a bronze plaque with a suitable inscription expressive of their grateful acknowledgments of his services should be presented to Sir Michael Foster. It was also resolved to send a telegram to the Queen Mother in the name of physiologists of all nations thanking her for the impulse given to the study of human physiology through the

construction at her initiative of the physiological laboratory on the top of Monte Rosa. Another telegram was despatched to the Minister of Public Instruction, Signor Nasi, thanking him for a subsidy which he had granted towards the organisation of the same laboratory. The scientific communications presented to the Congress were so many that those actually read had to be cut down to about one-half of the total number. The real business began on the second day of the meeting. Amongst the most interesting and well received of the papers contributed on that day were those of Professor Langley of Cambridge and Professor Sherrington of Liverpool, the former being on the Action of the Inhibitory Cardiac Fibres of the Vagus, the latter on the Comparative Excitability of the Cerebral Cortex in Monkeys and in Anthropoid Apes, a short abstract of which appeared in our issue of Oct. 5th. On the third day Mr. W. M. Bayliss of London demonstrated certain new and remarkable facts which he had observed in regard to the functions of the posterior spinal nerve roots in the production of vascular dilatation. Professor Langley on the same day gave another important demonstration regarding the action of nicotine on the substance of nerve ganglia, and Dr. Waller of London exhibited numerous photographs illustrating the electro-motor phenomena in various organs (the skin, the eye, and the electric organ of fishes), tending to show that every living tissue has the property of developing an electric current capable of detection by the galvanometer. Various experiments were shown in confirmation of the theory. During this day's sitting the presentation to Sir Michael Foster of the commemorative plaque was made amidst much enthusiasm. On the fourth and last day Dr. Locke of London aroused much interest by a beautiful demonstration of a method of keeping alive a rabbit's heart after its removal from the body by means of an artificial circulation through the cardiac vessels. It would occupy too much space to refer to the many other communications of equal importance by physiologists of other nationalities, and we have therefore spoken only of the English contributions. For scientific results this Congress will compare favourably with any of its predecessors, while for the interest of its proceedings it will stand out before all of them on account of the remarkable number of practical demonstrations and experiments with which each paper was illustrated. Among the social attractions of the Congress were a banquet, with the usual long toast and speech list, and a reception at the Communal Palace by the Syndic of Turin.

#### PROGRESS OF THE ANTI-MOSQUITO CAMPAIGN IN SIERRA LEONE.

DR. LOGAN TAYLOR, now carrying on operations against mosquitoes in Freetown on behalf of the Liverpool School of Tropical Medicine, reports on Sept. 17th that from the beginning of the work 6500 houses have been cleared of broken bottles, tins, calabashes, and the like, in which culex mosquitoes breed. Drainage operations against anopheles mosquitoes are also being pushed as much as the rain will allow. He adds: "I think there is no doubt but that the number of anopheles in the streets which we have dealt with is diminished. The people resident in the streets will tell you that at once. The number of pots and tins removed has made a considerable diminution in the culex." Dr. Taylor does not mention the number of cartloads of pots and tins removed, but from previous averages it may be put at something like 1300. Considering that the work had been in progress at the date of report for little over two months and has been much impeded by floods of rain the results are already very satisfactory. In addition to 50 other men two men are specially employed to look constantly after the centre of the town, where the offices, warehouses, and European houses are. The Governor, Sir Charles King,

Harman, is giving every assistance. Dr. C. W. Daniels, of the London School of Tropical Medicine, who has been studying Dr. Taylor's work at Freetown and has now returned to England, says in a letter to Major Ross: "In my opinion already your efforts have been crowned with a large degree of success, as there has been a noteworthy diminution in the number of the first two genera of mosquitoes (anopheles and a kind of culex) found in the houses. The number of breeding-grounds has been enormously diminished."

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Oct. 2nd states that for the week ending Sept. 28th there was but one case of plague reported in Cape Colony, that of a person in the class of those under naval and military control—namely, a native in the remount camps at Port Elizabeth. There was 1 death, that of a native at Port Elizabeth. The area of infection remains unchanged. As regards the Mauritius a telegram from the Governor received at the Colonial Office on Oct. 4th states that for the week ending Oct. 3rd there were 54 cases of plague and 36 deaths. As regards Egypt, during the week ending Sept. 29th 4 cases of plague and 1 death from the disease have been reported from all Egypt. Of these cases 3 occurred among Europeans and 1 case and 1 death among the natives. From Alexandria 3 cases and 1 death were reported, and from Port Said 1 case.

#### ELIGIBLE BUILDING SITES!

THE conditions which apparently are responsible for the outbreak of scarlet fever in the Horton Grange district of Bradford are not without parallel elsewhere, while they show that the attention of local authorities when directed to new buildings erected in their districts should not be confined to the details of the structures to be erected. Dr. W. A. Evans, the medical officer of health of Bradford, has informed the Health Committee of the corporation that the outbreak is, in his opinion, due to what a head-line in a local newspaper describes as the "tipping system." This term does not refer to any alleged venality on the part of the sanitary authority, but describes a method resorted to for filling up depressions in ground which is destined to be built upon. We are most of us familiar with the aspect of these depressions, for we can hardly leave London and other large centres of population without seeing them from the railway-carriage window as we travel through the suburbs, and the method of filling them up which has prevailed at Bradford is not confined to that town. The depressions have usually been caused by the digging of ballast for railways, of road-metal, or of clay for the making of bricks for new suburban buildings, and the method adopted to fill the depressions when more building land is required is that of "tipping" as they phrase it at Bradford, or of "dumping" as our American cousins would call it, ash-pit refuse from the neighbouring urban district into the hollows which are frequently of considerable depth. It is quite clear that ash-pit refuse, which, of course, does not consist only of ashes, is in itself about as unsuitable a soil to build dwelling-houses upon as could possibly be invented, and a second cause has been found to operate at Bradford to foster the spread of disease in such tenements, for ash-pit refuse naturally subsides unevenly under the weight of a house, with the result that drain-pipes are broken and displaced and the conditions for the inhabitants of the houses built upon refuse become even worse than before. We note that the Bradford Health Committee hope that the Cleansing Committee will discontinue the practice of tipping refuse in the neighbourhood and also hope that the Building Committee will insist upon precautions such as concrete floors

where refuse is built upon. It would be better, however, if the Bradford Corporation acting as a unanimous whole would embody the wisdom of its committees in measures for the disposal of refuse without tipping it into the Horton Grange or any other district, for concrete floors and foundations will merely partially protect the immediate neighbourhood of a house or cottage and will never make wholesome land out of the contents of scavengers' carts. Other methods of levelling such sites as those described will have to be adopted and the outbreak of scarlet fever at Bradford will have served a useful purpose if it proves a timely warning to local authorities there and elsewhere.

THE honorary secretaries of the Prince of Wales's Hospital Fund for London have received at the Bank of England the sum of 100 guineas from the King, who has been pleased to continue the annual subscription which His Majesty, as Prince of Wales, has hitherto contributed to this Fund.

AN address will be given by Mr. Thomas Bryant at Queen's Hospital, Birmingham, on Oct. 18th, at 4.30 P.M., on the occasion of the first distribution of clinical prizes since the University commenced work.

AT the quarterly meeting of the Directors of the Naval Medical Supplemental Fund held on Oct. 8th, Sir J. N. Dick, K.C.B., in the chair, the sum of £45 was distributed among the several applicants.

THE Harveian Oration will be delivered before the Royal College of Physicians of London on St. Luke's Day, Friday, Oct. 18th, at 4 P.M. by Dr. Norman Moore.

#### THE LATE AMIR OF AFGHANISTAN.

BY JOHN ALFRED GRAY, M.B. LOND.

THE report of the Amir's death has been officially confirmed; one may therefore accept it as true. So many times has his death been reported that one hesitated to accept the news as final till the official confirmation arrived. It is not that his death is an unexpected occurrence, but the news has been expected for so many years that one marvels that he has lived so long. I remember the last time I had the honour of attending His Highness during an illness, and I placed (in my own mind) his probable duration of life at two years; this was in 1890. I will endeavour to describe the condition that I found him in.

It was late one night in the autumn of 1890 that I was summoned hastily to the palace. There was a hammering at the gates of my courtyard which woke me, and immediately a servant came running to my room saying, "Up, Amir Sahib calls." One does not linger on these occasions. I found my horse saddled and bridled at the gate, and accompanied by the two horsemen who called me I rode off through the bazaars. The gleam of an occasional oil-lamp in the rain puddles made the darkness visible. Presently a clatter of hoofs showed my interpreter hurrying after us. This was satisfactory; for the two men might have been playing the part of "the Thing that walks by night," in which case I should not have been seen again. This happens at intervals in Kabul. We reached the palace, and leaving our horses at the gate hurried through the gardens to the Amir's pavilion.

I found His Highness lying on a couch, rolling his head from side to side and groaning. Malek, the favourite page-boy, was rubbing the right knee. The room was brilliantly lit with candles and around were kneeling Prince Habibullah and his brother and the chief officers of State. Receiving the Amir's command, I proceeded to examine into his condition. The right shoulder, elbow, wrist, and knee were swollen, red, and very painful. Every few minutes he was passing a few drops of scalding urine, his breathing was hurried, and his pulse quick and weak. His throat was sore and inflamed. There was a crepitant patch on the left axillary line. The heart was somewhat enlarged, but I heard no murmur. His

temperature, to the best of my recollection (for I am writing without notes), was 102.4° F. His urine was loaded with albumin and he had not slept for days. But this was not all. It appears that he had been ill for some weeks under the care of hakims. He had been treated with many violent purges, much leeching, and copious bleedings, and his gouty foot had been frequently plunged into ice-and-water to relieve the pain. Altogether his condition appeared to me serious—more than a little serious, for I was informed by those friendly to me that my life depended on his. I therefore considered what I should do. A lamp was brought and with a page-boy—the foster-brother of Prince Habibullah—I went to the hospital to get what drugs I needed. These were given into the charge of the lad. He was in future to be responsible for them and to give them out only to me.

To be brief, I gave His Highness diaphoretics with salicylate of potash, which I made fresh for every dose. His Highness, after the Mahomedan custom, uttered a short prayer before he took the first dose. I did also. The medicine had a most satisfactory effect in relieving the pain and procuring sleep. The improvement being so obvious it was interesting to note the delight of all, from prince to page-boy. I have a sheaf of letters of congratulation by me from the Sultana and Prince Habibullah, to whom I had every morning to send a report. The politeness and distinction with which I was treated by everyone may be imagined. But this was not the end. Towards the end of the week I gradually dropped the use of salicylate on account of its depressing effect and one night there was some return of pain.

There was a person at the Court—a Hindustani—who was unfriendly to me and he seized this opportunity of whispering to the Amir what he could that would prejudice me with His Highness, saying that I was giving him "shrab" in all his medicines which must inevitably make him worse in the end, and so on. The Amir was weak with long suffering—he had had a return of pain—and he believed this person. I was informed in the morning, five days after I took the case in hand, that my treatment would be suspended for the present. The hakims were reinstated. What can one do under circumstances so exasperating? The hakims knew no medicine or pathology; they were again in charge of a life on which mine hung and they were likely to terminate it. Reasoning would have no effect; my statements would not appeal to the Oriental mind. I decided, therefore, to accept the inevitable, but I thought that I would shoot that interfering person who was my enemy. I said so; and he kept out of my way. His interpreter, however, told me that I should lose caste by shooting one of low degree. I, of course, would not have shot him—one does not do such things in cold blood. At this time the Sultana was taken ill and I had the Amir's order to attend her in the harem serai. From Her Highness and the page Malek I heard how it was that I had been suspended.

To cut a long stay short—for even now I do not care to recall too vividly to my recollection the anxious weeks that followed—His Highness, after a period of considerable danger and suffering, during which I was allowed to watch his progress daily, made a tedious recovery, and I was permitted to return home on leave for some months bearing with me a substantial token of the Amir's goodwill.

I read that Prince Habibullah has the arsenal and treasury, and consequently the power, in his hands. It is a blessed thing for Afghanistan if it is so, and for England too, so far as I can judge. The death of the Commander-in-Chief, Gholam Hyder Khan, deprives the Sultana of her greatest supporter, so that the probability of a revolution in favour of her young son, Prince Mahomed Omer (who is Royal on both sides), is vastly lessened. This lady, however, is a source of probable danger to the peace of Afghanistan—that is, if she is still living.

Habibullah always struck me as a good fellow—intelligent, well-mannered, and distinctly favouring the English. He was learning English when I was in Kabul and could speak a little even then. He seemed a milder and smaller copy of the able, courteous, chivalrous, crafty, and fierce Prince, his father, whose strong personality had such a glamour that he attracted not only the respect, but even the affection, of us who were in his service. I have the recollection of many great kindnesses from my late Royal master (and of some injustices), and I wish his son the Prince Habibullah every success for the sake of his country and ours in the difficult and dangerous task before him.

Baling.

## Looking Back.

FROM

THE LANCET; SUNDAY, OCTOBER 12, 1823.

*Extract from a Surgical Lecture delivered by Sir ASTLEY COOPER, Bart., at St. Thomas's Hospital on Oct. 8th, 1823.*

The next subject is

INFLAMMATION. There are four signs that commonly attend it, viz. redness, pain, increased heat, and swelling.

First, redness. This arises from an increase of the red particles of blood in the part; this is particularly exemplified in the white of the eye during inflammation.

Second, swelling or tumour is owing to the greater determination of blood to the affected part; it is not altogether owing to this circumstance, but arises in a great measure from an effusion of serum into the cellular membrane; a portion of this coagulates; hence the hardness of the inflamed part.

Third, increased sensibility is owing to distension of the nerves. Parts naturally insensible are quite the reverse when in a state of inflammation. Sir Astley was called a short time since to a case where it was requisite to saw off a piece of bone; during the operation, he opened a cavity in which was a small piece of bone and a fungus; the latter was extremely sensitive; extract of belladonna applied to it gave instant ease. Bones, though destitute of sensation in their healthy state, are dreadfully painful when inflamed. It is exceedingly improper to perform operations upon parts when inflamed.

The fourth is increased heat.

Mr. Hunter denied this: he introduced a thermometer into the opening when operating for hydrocele, and it rose to 101; after 24 hours it was no more than 100. Though no increase of heat is evinced in internal inflammation, yet when the malady is on the surface of the body, an alteration of seven degrees takes place; as on the inside of the thigh, where a blister was applied, the thermometer rose to 90, while on the inside of the opposite thigh it only reached 83.

Inflammation has four terminations.

First, adhesion. This arises from coagulable lymph being thrown out into the cellular membrane, and the parts become glued together.

Second, suppuration, or secretion of matter. This is composed of particles nearly similar to those of the blood swimming in a fluid which supports them and this fluid coagulates.

The third is absorption or ulceration, which eventually arises from continued pressure, thereby allowing the escape of the extraneous body.

The fourth is the destruction of life. Enfeebled by excessive action, the blood towards the extremities becomes coagulated, and gangrene is formed.

The constitutional effects are similar to those of the disease mentioned in the last lecture.

The inflammation is healthy or unhealthy. No wound can be restored without the former: even the little wound made in bleeding would inevitably destroy life, were it not for this salutary principle. A slight inflammatory action throws out upon the edges of the wound adhesive lymph, by which the edges are permanently united.

When a ligature is put upon a large artery, unless inflammation supervened, it could not be of any use; the first thing nature does in this case is to form a clot of blood at that part of the vessel where it has been tied, inflammatory action taking place, adhesive matter is thrown out, and the plug of blood and internal coats of the artery become firmly glued together, so as to prevent the possibility of hemorrhage when the ligature comes off: should the constitution be in an unhealthy condition, however, this process would not be executed, so that upon the ligature's coming off, the person might die of hemorrhage. Spontaneous inflammation is generally unhealthy.

Sir Astley concluded by observing, that he had expected to have reached the subject of specific inflammation; but as there was not time, he would begin it on Monday next.

## THE ARMY AND INDIAN NURSING SERVICE.

MR. BRODRICK'S Committee appointed to consider the Reorganisation of the Army and Indian Nursing Service, consisting of the same members as the Committee on the Reorganisation of the Army Medical Services, has drawn up the following report :—

### SCHEME FOR THE REORGANISATION OF THE ARMY AND INDIAN NURSING SERVICE.

1. There shall be one Military Nursing Service for His Majesty's Army in the United Kingdom, India, and the Colonies, to be designated "Queen Alexandra's Imperial Military Nursing Service" (Q.A.I.M.N.S.). In this service shall be amalgamated the existing Army Nursing Service and the Indian Nursing Service.

2. Her Majesty Queen Alexandra shall be requested graciously to assume the presidency of this service.

3. The Nursing Service shall be under the immediate control of Her Majesty Queen Alexandra as president, and of a Nursing Board constituted as follows :—

President.—Her Majesty Queen Alexandra.

Chairman.—The Director-General, Army Medical Service, or an officer nominated by him.

Two members of the Advisory Board, Army Medical Service, of whom one shall be a civilian.

The Matron-in-Chief, Queen Alexandra's Imperial Military Nursing Service.

Three matrons of large civil hospitals with medical schools.

One representative of the India Office to be appointed by the Secretary of State for India.

Two members to be nominated by Her Majesty the President, and holding office for three years.

4. Upon this Nursing Board the civilian members of the Advisory Board, Army Medical Service, and the matrons of civil hospitals shall be appointed by the Crown, on the advice of the Secretary of State, and shall hold office for a period of three years, renewable on expiration of the term of appointment.

A matron of a civil hospital shall receive an honorarium of £26 5s. per annum while serving on the Board.

5. The Nursing Board, of which three shall form a quorum, shall usually meet at fortnightly intervals. The minutes of the proceedings of the Nursing Board shall be laid by the Matron-in-Chief before the Advisory Board. It shall be in the power of the Advisory Board to refer back any point to the Nursing Board for reconsideration, and in case of a divergence of opinion between the boards, the matter in question shall be referred to the Secretary of State.

6. Subject to the general control of the Advisory Board the Nursing Board shall be responsible for—

(1.) Advising the Secretary of State upon the strength of the nursing staff of various grades requisite in each military hospital (including the hospitals for women and children attached to military stations), having regard to the character of the cases admitted, and subject to the proviso that as a general rule hospitals containing fewer than 100 beds will not be provided with a regular female nursing staff (*vide* paragraph 14).

(2.) Defining the conditions under which nurses may enter the service, the terms of their appointment, and the duties to be performed in the several grades of the Nursing Service.

(3.) Dealing with all questions relating to the uniform and clothing allowance of the Nursing Service.

(4.) Receiving and considering reports from the Matron-in-Chief and the matrons of the various hospitals.

(5.) Recommending to the Commander-in-Chief, for the approval of the Secretary of State, the appointment, retention, promotion, retirement, dismissal, and distribution of the members of the Nursing Service.

(6.) Arranging for the selection and engagement of additional nurses, the organisation of the requisite nursing staff, and the appointment of principal matrons in case of war or epidemic.

(7.) Advising the Secretary of State upon the formation of the Nursing Reserve of the Queen Alexandra's Imperial Military Nursing Service.

(8.) Arranging for the periodical inspection of military hospitals as regards nursing efficiency.

(9.) Submitting to the Secretary of State, through the Advisory Board, a scheme for the organisation and development in India of the Queen Alexandra's Imperial Military Nursing Service, which shall allow for adequate local control, subject to the general authority of the Nursing Board.

7. The Queen Alexandra's Imperial Military Nursing Service shall consist of—

(1.) A Matron-in-Chief and Principal Matrons.

(2.) Matrons.

(3.) Sisters.

(4.) Nurses.

8. All matrons, sisters, and nurses of the Queen Alexandra's Imperial Military Nursing Service shall be entitled to wear an appropriate badge which, by special permission only of Her Majesty the President, may be retained by the wearer after leaving the service.

9. The Matron-in-Chief shall have a seat on the Advisory Board, acting as a member of the Board whenever matters concerning the Nursing Service are under discussion, and in her absence a principal matron shall take her duties.

10. The Matron-in-Chief shall be the medium of communication between the Director-General and the Queen Alexandra's Imperial Military Nursing Service, in all matters connected with that service.

11. The Matron-in-Chief shall be responsible for keeping the service records and confidential reports from the matrons of the various hospitals regarding the character, conduct, and efficiency of the sisters and nurses under their control.

12. The Matron-in-Chief shall keep herself acquainted with the administration of the nursing service in the various military hospitals.

13. She shall submit to the Nursing Board recommendations for the appointment, promotion, retirement, dismissal, and distribution of members of the service.

14. She shall be responsible for maintaining a sufficient staff of special nurses, detailing them for duty in cases of emergency, or for service in smaller hospitals.

15. She shall present every year to the Nursing Board a scheme for the annual leave of matrons and special nurses, and shall report to the Board the arrangements made by matrons for the annual leave of sisters and nurses.

16. Amongst the duties of a matron, to be defined in detail by the Nursing Board, shall be the following :—

(1.) To recommend suitable candidates for admission to the service in accordance with the prescribed regulations.

(2.) In conjunction with the medical officer in charge of the hospital to forward to the Matron-in-Chief such confidential reports with regard to the work and conduct of the nursing staff as may be required, and to make recommendations for retention, promotion, retirement, and dismissal.

(3.) To be responsible for the general nursing arrangements of the hospital, for the due performance of their duties by the sisters and nurses, and for the maintenance of good conduct, efficiency, and discipline amongst all members of the female nursing staff. In conjunction with the medical officer in charge of the hospital to report upon these matters at stated intervals to the Nursing Board through the Matron-in-Chief.

(4.) To exercise similar functions as regards the hospital for women and children in a station where such hospital exists.

(5.) In urgent cases to provide, where practicable, for the nursing of women and children on the married establishment.

(6.) To engage and dismiss the female servants appointed to attend upon the nursing staff, and to be responsible for their discipline, good conduct, and efficiency.

(7.) To undertake the daily inspection of the nurses' quarters to ensure that they are clean, well ventilated, and kept in good order.

(8.) To be responsible to the medical officer in charge of the hospital for sufficient supply, good condition, and cleanliness of the bedding and linen in the nurses' quarters and the wards under her nursing charge.

(9.) To see that proper medical and nursing attendance is

provided without delay for sick members of the nursing or female domestic staff.

- (10.) To arrange the annual leave of sisters, nurses, and female domestic staff, reporting thereon to the Matron-in-Chief.

17. A principal medical officer shall report annually to the Nursing Board, through the general officer commanding, upon the conduct and efficiency of the matrons of hospitals within his district.

18. Amongst the duties of a sister in charge of a ward, to be defined in detail by the Nursing Board, shall be the following:—

- (1.) To be responsible for the cleanliness, ventilation, and good order of her ward and its annexes.
- (2.) To attend the medical officers in their visits to the ward, and carefully to carry out their orders with regard to the diet and treatment of patients.
- (3.) To see that the nurses and orderlies perform their duties punctually and efficiently, reporting any breach of discipline or neglect of duty on the part of a nurse to the matron, and on the part of an orderly to the medical officer in charge of the ward, or in his absence to a warrant or non-commissioned officer of the Royal Army Medical Corps.
- (4.) To take part in the nursing of all patients seriously ill.
- (6.) To be responsible to the matron and medical officer of the ward for sufficient supply, good condition, and cleanliness of the bedding and linen, and for the personal cleanliness of the patients.

19. Amongst the conditions under which nurses may enter the service, and the terms of their appointment (to be defined in detail by the Nursing Board) are the following:—

- (1.) A candidate must be of British parentage, be between 25 and 35 years of age, and possess a certificate of not less than three years' training and service in medical and surgical nursing in a civil hospital recognised by the Advisory Board. She shall be required to satisfy the Nursing Board that as regards education, character, and social status she is a fit person to be admitted to the Queen Alexandra's Imperial Military Nursing Service.
- (2.) If provisionally accepted she shall be placed on probation for a period of three months, at the end of which time, if her work and conduct are reported to be satisfactory by the matron of the hospital, she may, after having been medically examined, enter into an agreement binding herself to three years' service in the Queen Alexandra's Imperial Military Nursing Service and undertaking to conform to the rules and regulations of the service. The agreement shall be dated from the time at which the nurse was provisionally accepted, and may, on the recommendation of the Commander-in-Chief, be terminated at any time by three months' notice from the Secretary of State, or in case of grave breach of discipline or misconduct, without notice.

- (3.) On the expiration of her three years' term of service a nurse may be permitted—

(a.) To retire from the service.

(b.) To continue in the service as a staff nurse, with an agreement terminable at any time by one month's notice on either side.

(c.) To join the staff of special nurses under the orders of the Matron-in-Chief, with an agreement terminable at any time by one month's notice on either side.

(d.) To offer herself for promotion to the post of sister, undertaking to serve for at least one year, and afterwards under an agreement terminable at any time by one month's notice on either side.

(e.) To enter into a fresh agreement for service as nurse or sister in India, or elsewhere abroad, for a period of three or five years, according to climate.

20. All present members of the Army and Indian Nursing Service, and members of the Army Nursing Reserve who have been in military employment during the war in South Africa, shall be eligible for appointment in the Queen Alexandra's Imperial Military Nursing Service if recommended by the Nursing Board. Should any question arise as to their status in the Queen Alexandra's Imperial Military Nursing Service the Nursing Board shall report thereon to the Advisory Board, and the recommendation of the Advisory Board shall be submitted to the Commander-in-Chief, whose decision shall be final.

21. Any present member of the existing services who is

not retained in the Queen Alexandra's Imperial Military Nursing Service may be recommended for a gratuity of one month's pay for each year of service, if she is not entitled to a pension; and any member who may decline to accept the new terms of employment shall be allowed to serve upon the terms of her present engagement.

## 22. PAY.

### (a.) Nursing Staff—

Matron-in-Chief, £250 a year, rising by annual increments of £10 to £300, and lodging allowance.

Principal matron in India, £230 a year, rising by annual increments of £10 to £280, and lodging allowance.

Principal matrons, £110 a year, rising by annual increments of £5 to £160.

Matrons, according to size of hospital, £70 to £100 a year, rising by annual increments of £5 to £120 to £150.

Sisters, £37 10s. a year, rising by annual increments of £2 10s. to £50.

Nurses, £25 a year, rising by annual increments of £2 10s. to £35.

### (b.) Female servants—

£15 a year, rising by annual increments of £1 to £20.

## 23. ALLOWANCES.

### (a.) Nursing Staff—

Home station, board and washing, 15s. a week.

Station abroad, board and washing, 21s. a week.

Station abroad, washing, 3s. 6d. a week.

Home station, uniform, £6 per annum.

Station abroad, uniform, £7 per annum.

Home and abroad, cloaks, £2 per annum.

### (b.) Female servants—

Board and washing, 10s. 6d. a week.

24. Allowances at the recognised scale shall be given for Indian and Colonial service.

25. The regular annual leave of members of the Queen Alexandra's Imperial Military Nursing Service in home stations shall be as follows:—

Matrons, six weeks.

Sisters, five weeks.

Nurses, four weeks.

Leave at stations abroad shall be granted on the military system.

26. It is desirable that all members of the Queen Alexandra's Imperial Military Nursing Service should be eligible to apply for a pension at the age of 50 years, and should be retired at the age of 55 years. Rates of pension shall be according to the scale laid down in Article 1233, Royal Warrant for Pay and Promotion.

ST. JOHN BRODRICK.

E. W. D. WARD.

G. DE C. MORTON, Major-General.

JAMES WILLCOCKS, Colonel.

FREDERICK TREVES.

WILLIAM THOMSON.

W. R. HOOPER, Surgeon-General.

G. H. MAKINS.

HOWARD H. TOOTH.

ALFRED D. FRIPP.

ALFRED KEOGH, Lieutenant-Colonel, R.A.M.C.

ALEX. OGSTON.

E. C. PERRY.

H. E. R. JAMES, Major, R.A.M.C., Secretary.

## MEDICAL SCHOOL DINNERS.

*King's College Hospital.*—The annual dinner of the old students of King's College Hospital was held at the Hotel Cecil on the evening of Oct. 1st, the day on which the medical session was opened. The occasion was distinguished by the fact that an unusually large number of the senior old students were present. These included the chairman, Mr. Paul Swain of Plymouth, Mr. Christopher Heath, Colonel H. Cayley, I.M.S., C.M.G., Mr. Wharton P. Hood, Dr. A. B. Duffin, and many others who have gained a high position in practice. It was the fiftieth anniversary of the day upon which Dr. Duffin (who has recently retired from the staff of the hospital) entered King's College as a student, a circumstance which greatly attracted his friends and contemporaries to the dinner. The Rev. Henry Wace, D.D., the late Principal

of King's College, and the Rev. A. Robertson, the present Principal, were also present, and among the old students of more recent years were Sir John Alexander Cockburn, K.C.M.G., and Captain C. Vipan, D.S.O., gentlemen who have abandoned the practice of medicine and gained distinction in other fields, the former as a statesman in Australia and the latter as a combatant officer with the 3rd Buffs in South Africa. The members of the present staff of the hospital were nearly all present, while one or two of the old students had become qualified during the present year. In his speech the chairman alluded to the great past of King's College Hospital, as proved by the fact that each of the following old students, Mr. Christopher Heath, Mr. G. Lawson, Mr. N. C. Macnamara, Mr. W. Rose, and Mr. A. B. Barrow, is now senior surgeon to a London hospital, and as evidence that the eminence of the present staff is equal to that of their predecessors he mentioned the distinction of C.B. which has just been conferred on Mr. Watson Cheyne and Mr. G. Lenthall Cheate for their work in South Africa, and that Dr. G. F. Still has been appointed Gulstonian Lecturer at the Royal College of Physicians of London.

**Middlesex Hospital.**—On Oct. 1st, at the Trocadéro Restaurant, Piccadilly, a large and enthusiastic gathering of the past and present students of this institution was held. Of about 200 guests who accepted the invitation of the school council 174 were actually present. The chair was taken by Mr. J. Bland-Sutton who was supported by Lord Howard de Walden, who had distributed the prizes in the afternoon, and also by Alderman Sir William Treloar. After the loyal toasts had been honoured the toast of "The Services" was responded to by Lord Howard de Walden, who had taken an active part in the South African campaign, including the relief of Kimberley and subsequent operations. His Lordship spoke in high praise of the magnificent pluck and stoical endurance of the British soldier and the ever-ready skill and resourcefulness of the medical department. In speaking of the Middlesex Hospital and Medical School the chairman alluded with warm approval to the energy and grasp of modern requirements evinced by the Weekly Board and School Council in the equipment, maintenance, and extension of the hospital and school. This was emphasised in detail by the replies of Mr. G. B. Hudson, M.P., and the Dean. The former dwelt in his speech upon the recent opening of the new wing for the treatment and investigation of cancer and the enlargement of the wards in the north-east portion of the hospital. The Dean, though deploring the falling-off in the number of students which affected most, if not all, the London medical schools, congratulated those present on the quality of the men now turned out, alluding to the greater number attaining the higher degrees and recording the attainment of gold medals in medicine and anatomy in London University in the past year. The toast of "The Past and Present Students" was responded to by Mr. John Aekery, President of the Odontological Society of Great Britain, and by Mr. T. W. Scott, the senior Broderip Scholar of the year. The toast of "The Visitors" was proposed by Dr. William Duncan and responded to by Mr. Wilhelm Ganz who, with the assistance of Señor Guetary and Herr Kolni-Balozky, rendered an exquisite musical programme which added greatly to the success of the evening. The proceedings closed with the proposal of the Chairman's health by Dr. Sidney Coupland who alluded to his successive attainments in anatomy, morphology, and pathology.

**St. Mary's Hospital Annual Dinner.**—The St. Mary's Hospital annual dinner took place on Oct. 3rd in the Whitehall Rooms of the Hôtel Métropole. The guests of the evening were those members of the hospital, some 24 in number, who have recently returned from service in the South African war, and nearly 200 of the past and present students were there to do them honour. The chair was taken by Brigade-Surgeon-Lieutenant-Colonel A. B. R. Myers, who was supported by Sir William Broadbent, Mr. Edmund Owen, Mr. Herbert Page, Dr. D. B. Lees, Mr. G. A. Critchett, Mr. G. P. Field, Mr. H. E. Juler, Dr. M. Handfield-Jones, Mr. J. Ernest Lane, Mr. H. G. Plimmer, and Dr. H. A. Caley. The toasts of "The King" and then of "Queen Alexandra, the Duke and Duchess of York, and the rest of the Royal Family" were proposed by the Chairman in a few well-chosen words and were duly honoured. Mr. Page, who met with a great welcome, then proposed the toast of "The Imperial Forces." He remarked that this was the first occasion on which he had given the greater toast of "The Imperial Forces"; hitherto

it had always been "The Navy, Army, and Auxiliary Forces." This signalled a new phase in the expansion of our empire, the union of men of every country under one King. He referred with approbation to the new scheme for the reform of the Royal Army Medical Corps and declared that the medical schools must do their part: there must be no more boycotting of the service. St. Mary's, he said, had sent of her best to South Africa, and it was a great pleasure to him to propose the toast.—Fleet-Surgeon T. J. Preston responded for the Navy, Lieutenant-Colonel G. M. Giles, I.M.S., for the Army, and Mr. H. Stansfield Collier, V.M.S.C., for the Auxiliary Forces.—The Chairman then proposed the toast of "Prosperity to St. Mary's Hospital Medical School." He alluded to the honoured names of former members of the hospital staff and paid a graceful tribute to the exertions of Sir William Broadbent and Mr. Field on behalf of the school. He complimented the present staff on their success as teachers, and the students of to-day both on their achievement in the examination hall and on their prowess in the athletic field.—The Dean (Dr. Caley) responded for the school, and alluding to the effort on foot to complete the Clarence wing said that the board of management looked forward with every confidence to an early consummation of their endeavours. He also spoke in hopeful terms of the negotiations now in progress to provide a sports ground for the students.—Mr. Owen, in a characteristic speech, gave the health of those who had served in South Africa and paid an eloquent tribute to those who had fallen.—Thanks were returned by Mr. Wallace Ashdowne, surgeon to the Imperial Yeomanry Base Hospital; Mr. V. Warren Low, civil surgeon; and Mr. E. L. Jenkins, one of the dressers of the Welsh Hospital. A most successful evening was brought to a close by the toast of the health of the Chairman which was given by Sir William Broadbent and drunk with great enthusiasm.

(To be continued.)

## THE ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1900.

### SECOND NOTICE.<sup>1</sup>

ATTENTION has been directed to a curious practice which has sprung up amongst the manufacturers of textile fabrics by which they habitually defrauded their workpeople by paying them for a smaller quantity of work than that which they actually performed. In this case we were glad to be able to record the fact that by means of a statutory provision specially passed for the purpose this nefarious custom has been practically abolished. At the present time, however, it appears that the workmen in many cotton-mills suffer greatly from the dishonesty of their employers, who exact from them an amount of work considerably in excess of that for which they are actually engaged. Two inspectors, Mr. Crabtree of Oldham and Mr. Dodgson of Bury, call attention to this matter. The practice is an old one in the cotton trade, for Mr. Crabtree himself when a boy 30 years ago was subjected to the treatment. He points out, however, that the custom has become more general and that at the present time "nearly every cotton-mill cribs time." "Time-cribbing" is a well-known expression in the districts of Oldham and of Rochdale. The method adopted by the manufacturers is thus described: "In these defaulting factories the manufacturing process too often begins at 5.30 to 5.55 A.M., continues to 8.5 A.M., is resumed at 8.25 A.M., and stops at 12.35 to 12.37 P.M.; it begins again at 1.25 P.M., and continues to 5.35 P.M. There is thus over 30 minutes deliberate illegal overtime put in on each of five days in the week, and about 15 minutes on Saturday, or about 160 minutes per week. That is to say, the day hands in these factories have to work two and a half hours per week more than should be demanded of them, and for this illegal demand they do not even receive the recognition of payment." Mr. Dodgson says that the evil is almost entirely confined to the cotton factories and that in the Rochdale district the manufacturers of cotton fabrics are greater offenders than the spinners of yarns. In commenting on these reports Mr. H. S. Richmond,

<sup>1</sup> The first notice appeared in THE LANCET of Sept. 28th, 1901, p. 868.

His Majesty's superintending inspector of factories for the North-Western Division of England, suggests that the duties of inspectors would be simplified and the practice of time-stealing reduced if a fixed and substantial penalty could be exacted should the main engines be set to work before, or allowed to run after, the legal hours. In favour of this proposal he points out that "the engine-house is usually more accessible than the factory itself and the fact of its running more easy of proof than illegal work by individual hands." The matter appears to deserve the attention of the Chief Inspector. The present state of things seems to be most iniquitous. It is difficult at first sight to see why it cannot be remedied, but Mr. Dodgson's report contains this cryptic sentence "It [the evil] is difficult to detect because the whole community where it prevails is favourable to it." It is not easy to understand how those members of the community whose time is stolen (or "cribbed") without the "recognition of payment" can really be in favour of such a practice.

The report of the medical inspector (Dr. T. M. Legge) contains a table showing the number of cases of poisoning from lead which were notified. In this table the statistics for the last three years are given. The number of cases of lead-poisoning reported in the year 1898 amounted to 1278, in 1899 to 1258, and in 1900 to 1058. These figures, the medical inspector points out, are strictly comparable. Second notifications of persons already included in the return within the preceding 12 months are not regarded as fresh cases. In the year 1900 53 second notifications were made in the case of people who had been previously reported. In the year 1899 there were 52 such instances. The object of notification of "industrial lead-poisoning" is the subject of a memorandum by Dr. Whitelegge (Appendix 17, p. 119). This memorandum was issued in March, 1900, and is supplementary to one issued in December, 1898. It deals with the manner in which cases occurring in house painters and plumbers should be treated by the Home Office inspectors for statistical purposes and with the way in which recurring attacks of lead-poisoning should be notified. The object of notification is to obtain a clue to those conditions which are not only prejudicial to health but which are also conditions over which the factory inspectors can exercise control. Under the present law only those cases which occur from the effects of labour carried out in a factory or workshop are of interest to the inspectors, for the Home Office has no power beyond these limits. Lead-poisoning contracted in the course of any business which is not under the control of the Factory Acts obviously cannot, therefore, be dealt with under those Acts. Dr. Whitelegge justly points out that in the present circumstances it would be practically useless for such cases to be reported as any reports of the kind being non-statutory would be incomplete and would therefore have but little statistical value. The conditions under which the notification of lead-poisoning should be made are briefly that in the opinion of the medical practitioner (1) the patient is suffering from the disease and (2) that it was contracted in a workshop. In regard to the first of these points it may be well to mention that patients have been reported as suffering from lead-poisoning when the only sign pointing to the disorder has been the presence of a blue line on the gums. The question as to whether lead-poisoning was or was not contracted in a factory or workshop has frequently given rise to difficulty and to the expenditure of much time. The best example of such a case is that of a house painter. In the case of any ordinary journeyman the difficulty of course does not arise, for he is outside the protection of the Home Office. But if a house painter should spend part of his time in a factory or workshop, and is occupied in such work as the grinding of lead or of pigments, or in mixing lead paints, he immediately comes under the care of the Home Office and "the question may legitimately arise whether his case does not become reportable, seeing that the risk, though in minor degree, is incurred in the workshop as well as in the out-door work." In such cases an enormous amount of work which is often fruitless is not infrequently thrown upon the inspectors. It has happened that after laborious inquiry, not only by the inspectors but also by the certifying surgeons, no ground has been discovered for assuming that the poisoning was effected at the factory. Several of the inspectors in their reports write feelingly of the loss of time which has been caused by investigations of the kind described. Here, for example, are instances. "Much valuable time was wasted in making inquiries into

cases of lead-poisoning occurring among house painters." (Mr. Johnson, West London, p. 156.) "General work has been much hindered by the necessity of investigating cases of lead-poisoning, or alleged lead-poisoning." (Mr. Blenkinsopp, West London, p. 155.)

During the year 1900 not less than 199 cases of lead-poisoning amongst house painters and plumbers were reported—these were of course excluded from the total given by the medical inspector which contains only cases reported under Section 29 of the Act of 1895. It may be of interest to give the numbers of those affected in the case of the principal trades: china and earthenware, 200 (49 less than in the previous year); litho-transfer works, 10; glass-polishing, 7; smelting, 34; turning and enamelling, 16; file-cutting, 40; white lead, 358 (41 less than in the previous year); paints and colours, 56; coachmaking, 70; ship-building, 32; electric accumulation works, 33; other industries, 202. An excellent analysis of the reports on lead-poisoning by the certifying surgeons is given by the medical inspector (p. 435). In this table information is given as to the exact occupations in which the poisoning was contracted, and the cases are, as far as possible, classified as "severe," "moderate," and "slight." There is also a tabular statement of the chief symptoms present, from which it appears that in the case of men 83.2 per cent. had gastric symptoms, 12.9 per cent. suffered from anæmia, 4.7 per cent. from headache, 12 per cent. from paresis, 3.1 per cent. from cerebral symptoms, and 5.9 per cent. from "rheumatic" symptoms. It seems curious that gout does not occur in the list. The women suffered less from gastric symptoms, to about the same extent from anæmia, to a much greater extent from headache, very much less from paresis, and more from cerebral symptoms and from rheumatic pains. The medical inspector is of opinion that the slower form of lead-poisoning brought about by the absorption of metallic lead and of the lead salts in the form of paint produces a more serious condition than that which is caused by the inhalation of dust or of fumes. Severe cases amongst file-cutters and coach- and ship-painters are common. The importance of both the age distribution and of the amount of time relatively spent by the different classes of workmen in the respective trades deserves consideration in this connexion. The following table is quoted as the most ready method of making these matters clear:—

Source of poisoning.	Age.		Duration of employment.	
	Under 30 years.	30 years and over.	1 to 5 years.	5 years and over.
	Per cent.	Per cent.	Per cent.	Per cent.
Metallic lead ... ..	43.0	57.0	37.4	62.6
Salts of lead as paint	43.6	57.4	45.8	55.2
Salts of lead as dust	65.4	34.6	76.0	24.0

A study of the table considered in the light of a knowledge of the processes of the trades in which lead and its salts are used shows the preventive measures which should be adopted. The immediate removal of the dust is the essential preventive measure in china and earthenware factories, in places at which processes connected with white and red lead are carried on, in paint and colour factories, in all work-rooms in which operations of litho-transfer are conducted, and wherever iron plates are enamelled. The medical inspector is of opinion that 90 per cent. of the cases of poisoning which occur in these trades are due to neglect in the immediate removal of the dust, some of which therefore is inhaled by the workers. In trades in which metallic lead paints are used the essential point is that the workmen should wash. In such trades Dr. Legge believes that 90 per cent. of the cases of poisoning are due to the absence of this simple precaution. In this matter the workmen are often to blame. In some cases, however, the employers have been distinctly at fault. A rather interesting case to the point is reported by the inspector for the North-western division of England (p. 304), but unfortunately it was not fought out to the end. A brass finisher brought an action in the Manchester County Court before His Honour Judge Parry to recover damages from his former employers because he had become poisoned by lead

in the course of his work. He had in the ordinary course of his occupation to use white lead for the purpose of putting fittings together. After the fittings were put together he had to suck them with his mouth to see if they were airtight or not. A pump ought properly to have been used for this purpose but the one instrument provided was suitable for large work only. Under the Factory Acts the employers are required to provide suitable washing appliances for the use of the workpeople. The plaintiff in cross examination admitted that a bucket was provided in which they could wash and that they could have soap if they asked for it and there were some "fents" in the room to serve as towels. The judge remarked that the Act required suitable lavatory accommodation. "Suitable washing conveniences should be supplied," he said, "but there were nothing but inconveniences apparently." The case ended by the payment to the plaintiff of £45 and costs.

The medical inspector has done much to bring the importance of washing prominently to the notice of lead-workers. A leaflet on "Lead-poisoning: How Caused and How Best Prevented," has been written, and no less than 10,000 copies have been distributed to those chiefly interested in the matter. The leaflet contains a great deal of excellent advice clearly given. One paragraph might, perhaps, with advantage have been put differently or omitted. It bears on the importance of not inhaling or swallowing lead and is preceded by an excellent sentence: "Carefulness while at work and cleanliness offer the best means of escaping attacks of lead-poisoning." The writer of the pamphlet then proceeds to say, "Those who work in lead should keep in mind every hour of every working day the importance of not breathing lead-dust and not carrying lead to the mouth in any way." Such a constant thought would hardly lead to a happy mental state.

The number of printers who suffered from plumbism during the year 1900 was 17, eight less than the number affected during the preceding year. Of those affected 10 were compositors, four were linotypists, two were stereotypers, one was a tyre rubber, and a case also occurred in a man employed in sweeping up the filings which dropped from a linotype machine. The medical inspector deprecates "the pernicious habit which many compositors have of holding the type between their teeth." It is certainly a dangerous habit and we may hope that it is not a common one amongst a most intelligent class of men.

The incidence of cases of poisoning amongst workers in white lead shows only a slight decrease, and periodical medical examination is said to be ineffective as a means of producing improvement partly because of (1) the low stratum of society from which the workers are drawn, and partly because (2) the threat of suspension is not so deterrent as in other branches of industry in which lead is employed. White lead workers are often a casual shifting race, whereas the skilled work employed in the Potteries is a well-paid profession not lightly to be given up.

A considerable improvement has been recently brought about in the earthenware and china industries. The number of cases of lead-poisoning reported in the year 1899 was 249, in the year 1900 it was 200. The statistics for the latter year show that the total number of people employed in the process of dipping amounted to 2265, and the number of those engaged in other branches of the work to 6372. Of the dippers 123, a proportion of 5.4 per cent., were affected by lead-poisoning. Of the other workers 200 were affected, a proportion of 3.1 per cent. These figures compare favourably with those of the previous year to the extent of 0.1 per cent. and 0.8 per cent. respectively. The principal improvement has taken place amongst the more skilled workers—the majolica-painters, the colour-dusters, and the glost-placers. The change for the better is seen throughout the whole of the districts engaged in the manufacture. A separate return is given showing for the Potteries district the number of persons employed in the different works and the number of cases of lead-poisoning reported to have occurred amongst them. In this list it is seen that in the case of majolica-painters the incidence of plumbism has been reduced from 4.7 per cent. in the year 1899 to 0.9 per cent. in 1900. The number of the skilled artisans is, however, small; it amounts only to 425, all of whom are women. The total number of people employed in this district in the various branches of the trade is 4857, and of these 165 suffered from plumbism, a proportion of 3.4 per cent., an improvement of 1 per cent. on the returns of the previous year.

Mr. J. F. Arlidge has made a series of inquiries to determine the effects of lead on pregnancies. He found that 239 women before they were engaged in working in lead bore 453 children, of whom 183 died. The total number of pregnancies was 487 and the number of miscarriages was 34. At the time during which they worked and after they had ceased to work in lead these women bore 499 children, of whom 182 died; the total number of pregnancies was 566 and the number of miscarriages was 67.

It is pleasant to be able to record the fact that a leadless glaze is coming into general use for the enamelling of iron hollow-ware, and that the number of glass-cutters who suffered from plumbism during the year 1900 was markedly less than that of those who suffered from it during the previous year (the exact numbers are seven and 19 respectively). On the other hand, the number of cases occurring amongst the manufacturers of electric accumulators is one in excess of that reported in the year 1899. Amongst those who work in the preparation of paints and colours the incidence of lead-poisoning is still severe. 30 factories are used for the work and over 82 per cent. of the cases occurred in those engaged in grinding and mixing pigments. Coach-builders also still suffer greatly from plumbism. 34 cases occurred amongst railway employés, and of these 19 occurred amongst the men of a large company on whose premises "the facilities for washing were bad." In making this statement it is reasonable to assume that the medical inspector desired to convey the idea that facilities for washing were absent or insufficient. In calico works it is stated that aniline dyes are taking the place of chromate of lead. A list of the fatal cases of lead-poisoning is given, but the enumeration of the symptoms from which the patients suffered is not sufficiently complete to make it of any clinical value.

## ELECTION OF DIRECT REPRESENTATIVES: CANDIDATURE OF DR. GLOVER.

A MEETING in support of the candidature of Dr. J. G. Glover was held on Oct. 4th at 1, Highbury-place, London, N. The chair was taken by Dr. G. Danford Thomas, who in his opening remarks urged the claims of Dr. Glover for re-election to the General Medical Council.

Dr. GLOVER said:—The importance of this meeting will turn rather upon what my constituents say than on what I say. But I must do my part in asking you to renew your support at another election. The General Medical Council is one of the best abused bodies in the profession. And it is all the better for a little criticism. If the critics are censorious and unreasonable it is they who suffer rather than the General Medical Council. As to my own claim to represent you, if you are not convinced of it by this time hardly anything I can say will convince you. But I trust that after hearing me you will see your way to that expression of confidence which has always served me in the past. It is in the very nature of the case that I must speak somewhat egotistically. I have to justify my existence. You will forgive any appearance of vanity. First, I should not be worthy to be a Direct Representative if I did not try to make medical education better. I believe that in its soundness and efficiency the great strength of the profession lies. Within a year or two of my election I tried to show the Council that there were gaps in medical education and that there were great groups of diseases not much seen by the student and in which he was not examined: that hospital practice was not general practice. In this I was fully supported by my then colleagues the Direct Representatives. The Council, and especially its leading members, gave us a fair hearing. We succeeded in getting the Government to throw the Metropolitan Asylums Board open to medical students. We secured, what I fear has been little acted on, the recognition of pupilage to a medical practitioner. Sir James Paget wrote to me on my views and said, "I see what you will do: you will add another year to medical education." That year, of course, has been added and the Direct Representatives have a full share of the responsibility and, as I think, the credit of the change. I said to a medical student a few months ago, "You are at the stage of your education described as walking the hospital." He replied, "I am walking five hospitals," and he made

good his statement by showing that besides his own hospital he was studying fevers at one hospital and insanity at another and that his tutor was very good in giving him clinical instruction at one or two hospitals to which he was attached. There are other questions which I must not pass over. There is the midwives question. I shall say a few words about it. I think it is a less burning question than it was in the last two elections, chiefly because I think that everybody sees that it must be settled. I do not myself care how simple the machinery is by which the new midwife is to be governed, nor do I care how simple her training is. I told the General Medical Council once, and I repeat, that if we could only secure that all midwives should know the value of clean hands and of puerperal cleanliness generally we should immensely reduce the mortality of lying-in women attended by them. In addition to this we could secure—as they do in every respectable maternity charity—that the women are to be made to understand the limits of their own functions and the obligation resting on them to send for a registered medical practitioner whenever the case of the mother or child presents any unusual features, we should have done nothing to impair the authority and the place of midwifery as a most important branch of medicine and we should have helped in a movement to increase the safety of lying-in women in childbirth. I have no objection to call this new midwife a “midwifery nurse,” though I think the Legislature would insist on the old word. A “nurse midwife” would be the best title, for it would indicate what is the fact—that the poor woman for whom alone this legislation is meant and for whom alone it can be justified, needs a nurse as well as a midwife. I wish to emphasise two points in my personal view of this question. First, that a Midwives Bill will be of little use if it does not stop the *practice* of midwifery by all women not certified or licensed. Until the last Bill it was only attempted to prevent the use of the title “midwife.” That, in my opinion, would be useless for the same class of women that make the Sarah Gamps would continue to exist and to attend the cases without calling themselves midwives. The next point on which I feel strongly is that it should be a part of this legislation for every district to provide and to pay registered medical men to respond to the call of the midwife. If it is fit for the State to provide gratuitous vaccination for the children of the poor it is surely equally reasonable to provide medical help for the mother in the hour of her peril. I succeeded in the Midwives Committee of the General Medical Council in getting this view adopted. But I did not succeed in getting the Council to accept it and undoubtedly the House of Commons will think twice, especially at the present time, before passing a clause which involves any addition to rates or taxes, however slight. But this is a very special case and one that should appeal to all parties. I must not spend more time on the midwives question. I should not have spent so much but for its human importance and the way in which it takes up the time and money of the Council. It would not be an exaggerated estimate to say that first and last our discussions on this subject have cost £1500 or £2000. We had one special session which cost between £600 and £700 to consider a Midwives Bill. The proposal for the creation of a Conciliation Board for the adjustment of disputes between medical aid associations composed chiefly of friendly societies and the medical profession has had, and if I am elected again will have, my warm support. Such a board must be formed outside of the Council; but it cannot be doubted that the support of the proposal by the Council and the great personal interest of the President, Sir William Turner, have greatly facilitated the realisation of such a proposal. The dispute between the Royal College of Surgeons of England and the Royal College of Physicians of London on the one hand, and the General Medical Council on the other, is an unhappy one, and one that the best friends of the General Medical Council will try to bring to a termination within the Council itself, and soon. I hold no brief for the Royal Colleges. I have always been surprised that the Royal College of Surgeons of England did not concede the reasonable degree of direct representation asked for by its members of whom it might well be proud. Such a refusal seems to me unreasonable and impolitic. But the matter under dispute at present between the Colleges and the Council is one that can only be settled amicably. Our own lawyers tell us that we have not the power to compel the Colleges to submit to our approval the institutions whose teaching in science they accept. The Colleges justly say that

they carefully inspect the institutions. We do not pretend that we have any means of doing so. It is not denied that in many of them chemistry, physics, and biology are well taught. My desire and endeavour will be to preserve or to restore the good understanding which has hitherto prevailed between the Colleges and the Council. Gentlemen, perhaps you will ask me what is the position and outlook of direct representation, and my reply shall be short. I see little immediate chance of any large increase of it. Parliament is terribly preoccupied with the war, and if once the war were ended there are other questions that would seriously compete with the demand for any amendment of the Medical Acts. But if we use direct representation well, and if the profession itself exercises the franchise already conceded to it, we may reasonably hope that the principle will be extended. There are various views entertained of the work and merit of the General Medical Council; according to some it has no merit, according to others it is a serious and powerful body. Be this as it may, it combines all medical authorities in its conferences and the Direct Representatives as well. So that meantime we do well to make much of it. It has improved education. It has raised the tone of professional ethics and of medical practice. It has abolished the unqualified assistant and by so much has enhanced the value of qualification. It has improved the feeling existing between the individual bodies and increased their mutual respect. By direct representation it supplies a link between the medical authorities and the General Medical Council. In all those ways it has benefited the public. For all these reasons the profession does well to regard it with respect and interest. I must be excused one personal word in closing. I do not know what the issue of the election will be. As regards myself I am struck with the attitude of confidence and kindness towards me throughout the profession and even including many who do not agree with me on all points. For one thing, whatever happens, I shall always have to be grateful—and that is the help and support of my neighbours. A man who has not this encouragement has little right to expect success. I have never lacked this support and I never had more evidences of it than I have had on this occasion.

SIR THOMAS BARLOW said that he attended the meeting with considerable diffidence and because he knew that it was to be a friendly meeting of fellow practitioners for the sake of conference and in order to learn something about the important questions that concerned the General Medical Council. The reason why so many people shirked medical politics was because they did not feel any direct concern in them. Men thought that the General Medical Council did not affect them, and having their own work to do said medical politics were no concern of theirs. But that was a very unworthy attitude to take up, for whatever concerned the humblest member of their profession concerned them all. There was a Nemesis that would come to them if they put aside the claims of their fellow practitioners. The manly and English thing to do was to take the trouble and pains to find out about these questions. There was a right and a wrong way, and they should try to carry the best man through to the General Medical Council and have things properly considered. If they did not address themselves to these questions and get to the bottom of them they would be taken out of their hands either by the Government or by the public, and both of these results would be a misfortune and a calamity. In regard to the midwives question was it not a scandal that it had lain so long on the table unsettled? Practical politicians recognised that there was a crying need calling for legislation to protect poor folks. If the profession kept the line that they had taken on this midwives question (for they were all in the same boat) it was a line of conduct rather like that of the dog in the manger. No impartial person who had listened to Dr. Glover could resist the conviction that the method that he and others had adopted was a sane method that brought the matter into practical politics. He considered that the midwives ought not to attempt any operative midwifery as that would be abominable. The midwives ought to have the power to call in some well-qualified practitioner to back them up in difficult cases. They ought to strengthen the General Medical Council and its members, especially those who took a practical, sane view. In regard to the friendly aid societies, however much they might dislike the conditions some line of action must be taken or the profession would be degraded. It was easy to sneer at the General Medical Council,

but anybody could sneer. What they wanted was someone to watch and to see the trend of public opinion. It was marvellous how rapidly social changes took place, and the position of their poorer brethren might be undermined in many ways right and left unless there were those who were on the *qui vive* and determined to defend them. They ought to make up their mind to secure the election of a good man to the Council, and he felt anxious that Dr. Glover should be elected because in choosing Direct Representatives they must have a man who knew what the life of a general practitioner was and who knew it in different ways. Further, they wanted a man who would not approach the question in any spirit of trade unionism. The great thing was to have these matters dealt with in the interests of the public because the interests of the profession were the interests of the public, and if the right thing were done for the public that would in the long run be right for the profession. Many of them perhaps did not agree with Dr. Glover in every line that he took, but he (Sir Thomas Barlow) was convinced that when Dr. Glover spoke on behalf of their craft he always bore in mind not only their interest but also the public interest. He did not think that any impartial person could have listened to the statement of Dr. Glover without recognising the tone of moderation, of practical politics, and of medical common-sense, that commended itself to the thoughtful practitioner. They wanted a Direct Representative who was alive to the danger of aimless and useless talk, and they wanted someone who recognised that the General Medical Council had limitations and could not do everything. Referring to Dr. Glover's remarks about the cost of talking on medical business at the General Medical Council, he said that it showed that Dr. Glover was alive to the great waste of money and that he wanted to work at something that was practical and within reasonable limits. Dr. Glover was well known to be practical, sensible, and moderate, and would not waste time or words, and for those reasons he had particular pleasure in proposing the following motion:—

That this meeting, having heard from Dr. Glover a statement of the work of the General Medical Council and of his views thereon, and having regard to his action in the three periods during which he has been one of the Direct Representatives of the profession in the Council, hereby expresses its unabated confidence in him and its determination to do all in its power to ensure his successful re-election.

Dr. J. FORD ANDERSON, in seconding the motion, said that the large number of practitioners who failed to vote at the election implied an appalling want of public spirit.

Dr. A. G. BATEMAN, in supporting the motion, said that owing to his peculiar official position he had particular reason for knowing Dr. Glover and his work. Dr. Glover was not a man of fancies or fads and was not easily biased by outside opinion. He would pay attention to what was said and would bring any matter before the General Medical Council if he thought it right to do so and would explain it to the Council with great tact and experience. With regard to the procedure of the General Medical Council he urged that by a new Medical Act the Council should have power to subpoena witnesses and should be empowered to administer the oath.

The motion was then put and was carried unanimously.

Dr. F. J. BUCKELL proposed, Mr. T. JAGO seconded, and Dr. W. A. MALCOLM supported the following motion, which was carried unanimously:—

That this meeting, believing that Dr. Glover's re-election will be in the interest of the profession generally as well as in that of the principle of direct representation, desires to commend his candidature to the heartiest support of all registered medical practitioners in England and Wales, who, it is hoped, will in their own interest, as well as that of the public, record a much larger vote at the coming election than on any previous occasion.

Dr. A. REID announced that promises of support had been received from the following, amongst others: Dr. James Adams, Eastbourne; Dr. F. H. Alderson, Bournemouth, formerly of London; Mrs. Garrett Anderson, London; Dr. Robert Barnes, consulting physician to St. George's Hospital; Mr. L. G. Barritt, Spalding; Dr. R. W. Batten, Gloucester; Mr. G. H. Biden, Penrith; Mr. C. W. Biden, Framlingham, Suffolk; Dr. G. H. Bishop, Wimbledon; Dr. J. Gordon Black, Harrogate; Dr. F. Milnes Blumer, Stafford; Mr. W. Percy Blumer, Sunderland; Mr. C. Braine-Hartnell, Stroud; Dr. J. W. Bramwell, Cheltenham; Mr. Edward Buckell, Romsey, Hants; Mr. J. L. Crisp, South Shields; Dr. George Easter, London; Mr. Hilton Fagge, Melton Mowbray; Dr. Joseph Frain, Newcastle-on-Tyne; Dr. R. Ritchie Giddings, Nottingham; Dr. J. Gill, Clifton;

Mr. A. Pearce Gould, London; Dr. Groves, Newport, Isle of Wight; Dr. James Hardie, Manchester; Dr. F. de Havilland Hall, London; Dr. T. F. Higgs, Dudley; Dr. A. Hollis, Freshwater; Dr. G. Petgrave Johnson, Stoke-on-Trent; Mr. H. W. Kendall, Clifton; Mr. G. Longbotham, Middlesboro'; Dr. Stephen Mackenzie, London; Dr. James Murphy, Sunderland; Dr. William Murray, Newcastle-on-Tyne; Dr. George R. Murray, Newcastle-on-Tyne; Dr. Frederick Page, Newcastle-on-Tyne; Dr. R. Paramore, London; Dr. Robert Peart, North Shields; Dr. Lloyd Roberts, Manchester; Mr. Thomas Rushbrooke, London; Dr. E. Markham Skeritt, Clifton; Mr. Rudolph Smith, Stockton-on-Tees; Dr. Smith, Newport, Essex; Dr. E. Mansel Sympson, Lincoln; Mr. B. Thornton, Margate; Mr. A. Primrose Wells, Beckenham; Dr. R. M. Witham, Burnley; Dr. James S. Williamson, Ventnor, and Mr. E. M. Wrench, Bas-low.

The following gentlemen were constituted a general committee for the promotion of the candidature of Dr. J. G. Glover as a Direct Representative: Dr. W. Danford Thomas, Mr. W. H. Kesteven, Dr. J. A. Glover, Dr. C. A. Ironside, Dr. A. Reid, Mr. G. F. Pollard, Mr. G. T. Keele, Dr. T. Hamilton, Sir Thomas Barlow, Dr. R. Paramore, Dr. A. G. Bateman, Dr. F. J. Buckell, Dr. Tice J. Budden, Dr. R. Hingston Fox, Mr. Thomas Jago, Mr. T. D. Jago, Dr. Alexander Morison, Mr. T. Hobbs Crampton, Dr. W. A. Malcolm, Dr. Ford Anderson, Mr. R. C. M. Pooley, Dr. Peter Harper, and Dr. Michael J. Bulger.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6378 births and 3435 deaths were registered during the week ending Oct. 5th. The annual rate of mortality in these towns, which had declined from 21.6 to 16.7 per 1000 in the six preceding weeks, further decreased last week to 15.6. In London the death-rate was 14.7 per 1000, while it averaged 16.2 in the 32 large provincial towns. The lowest death-rates in these towns were 10.8 in Bradford, 11.0 in Huddersfield, 11.3 in Derby, and 12.0 in Cardiff; the highest rates were 19.8 in Gateshead, 20.0 in Liverpool, 21.3 in Newcastle, and 23.1 in Sunderland. The 3435 deaths in these towns last week included 526 which were referred to the principal zymotic diseases, against 970, 732, and 634 in the three preceding weeks; of these 526 deaths 281 resulted from diarrhoeal diseases, 74 from diphtheria, 59 from "fever" (principally enteric), 41 from measles, 38 from scarlet fever, 30 from whooping-cough, and three from small-pox. The lowest death-rates from these diseases last week were recorded in Portsmouth, Cardiff, Swansea, Derby, and Huddersfield; and the highest rates in West Ham, Salford, Leeds, Sunderland, and Gateshead. The greatest proportional mortality from measles occurred in West Ham and in Wolverhampton; from scarlet fever in Preston; from whooping-cough in Plymouth and in Newcastle; and from diarrhoeal diseases in West Ham, Leicester, Salford, Burnley, and Gateshead. The 74 deaths from diphtheria in the 33 large towns included 30 in London, eight in West Ham, eight in Liverpool, five in Brighton, five in Hull, and four in Bristol. Three fatal cases of small-pox occurred in London, but not one in any other of the 33 large towns. There were 169 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, Oct. 5th, against numbers increasing from 13 to 163 on the seven preceding Saturdays; 51 new cases were admitted during the week, against 62, 37, and 44 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital, which had risen from 2994 to 3151 at the end of the four preceding weeks, had further increased to 3157 on Saturday last; 426 new cases were admitted during the week, against 457, 427, and 460 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 116, 124, and 137 in the three preceding weeks, declined again last week to 132, and were 72 below the corrected average. The causes of 41, or 1.2 per cent., of the deaths in the 33 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford,

Leeds, and in 14 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham-Liverpool, and Sheffield.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had decreased from 17.8 to 16.0 per 1000 in the four preceding weeks, further declined to 14.5 per 1000 during the week ending Oct. 5th, and was 1.1 below the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 9.1 in Greenock and 9.4 in Leith to 16.2 in Aberdeen and 16.4 in Dundee. The 463 deaths in these towns included 42 which were referred to diarrhoea, 14 to measles, seven to scarlet fever, seven to whooping-cough, six to diphtheria, and six to "fever." In all, 82 deaths resulted from these principal zymotic diseases last week, against 83 and 73 in the two preceding weeks. These 82 deaths were equal to an annual rate of 2.6 per 1000, which was 0.2 above the mean death-rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had been 53 and 42 in the two preceding weeks, were again 42 last week, and included 16 in Glasgow, nine in Dundee, seven in Aberdeen, four in Greenock, three in Paisley, and three in Leith. The deaths from measles, which had been five and 12 in the two preceding weeks, further increased last week to 14, of which 12 were recorded in Glasgow. The deaths from scarlet fever, which had been three, two, and four in the three preceding weeks, rose to seven last week, and included five in Glasgow. The fatal cases of whooping-cough, which had been 13 and seven in the two preceding weeks, were again seven last week, and included five in Glasgow and two in Edinburgh. The deaths from diphtheria, which had been three, four, and one in the three preceding weeks, increased again last week to six, of which three were registered in Glasgow and three in Edinburgh. The fatal cases of "fever," which had been 12, six, and seven in the three preceding weeks, declined again to six last week, and included three in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 79, 81, and 101 in the three preceding weeks, declined again last week to 77, and were 21 below the number in the corresponding period of last year. The causes of 19, or more than 4 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23.4 and 17.8 per 1000 in the two preceding weeks, rose again to 19.9 during the week ending Oct. 5th. During the past four weeks the death-rate has averaged 20.8 per 1000, the rates during the same period being 15.3 in London and 15.6 in Edinburgh. The 143 deaths of persons belonging to Dublin registered during the week under notice showed an excess of 15 over the number in the preceding week, and included 20 which were referred to the principal zymotic diseases, against 25, 30, and 17 in the three preceding weeks; of these, nine resulted from diarrhoea, eight from "fever," two from whooping-cough, and one from diphtheria. These 20 deaths were equal to an annual rate of 2.8 per 1000, the zymotic death-rates during the same period being 1.9 in London and 1.1 in Edinburgh. The fatal cases of diarrhoea, which had been 22, 20, and 11 in the three preceding weeks, further declined last week to nine. The deaths referred to different forms of "fever," which had been two, three, and three in the three preceding weeks, increased to eight last week. The 143 deaths in Dublin last week included 31 of children under one year of age and 37 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight increase over the respective numbers recorded in the preceding week. Three inquest cases and two deaths from violence were registered; and 40, or nearly one-third, of the deaths occurred in public institutions. The causes of 12, or more than 8 per cent., of the deaths in Dublin last week were not certified.

#### VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1901.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London.

With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 12.4 per 1000 of the population, provisionally estimated at 4,543,757 persons in the middle of the year. In the three preceding months the rates had been 8.5, 9.6, and 8.6 per 1000 respectively. The rates were considerably below the average in Kensington, Hammersmith, Chelsea, the City of Westminster, Wandsworth, and Woolwich; while they showed the largest excess in St. Pancras, Hackney, Finsbury, Southwark, Bermondsey, and Deptford. During the four weeks ending Sept. 28th, 157 cases of small-pox were notified in London, against 4, 22, and 94 in the three preceding months; 52 cases belonged to St. Pancras, 22 to St. Marylebone, 13 to Holborn, 12 to Finsbury, and 10 to Islington. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals at the end of September was 163, against 5, 13, and 74 at the end of the three preceding months; 174 new cases were admitted during the month, against 5, 19, and 93 in the three preceding months. The prevalence of scarlet fever showed a considerable increase over that recorded in recent months; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Hackney, Bethnal Green, Southwark, Bermondsey, Camberwell, and Greenwich. The Metropolitan Asylums hospitals contained 3096 scarlet fever patients at the end of September, against 2752, 3026, and 2971 at the end of the three preceding months; the weekly admissions averaged 412 last month, against 343, 355, and 288 in the three preceding months. The prevalence of diphtheria showed a marked increase over that recorded in the preceding month; the greatest proportional prevalence of this disease was recorded in Fulham, St. Pancras, Hackney, Holborn, Finsbury, and Deptford. There were 1499 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of September, against 1169, 1332, and 1336 at the end of the three preceding months; the weekly admissions averaged 248, against 175, 209, and 177 in the three preceding months. The prevalence of enteric fever was greatly in excess of that shown in any recent month; among the various metropolitan boroughs this disease was proportionally most prevalent in Fulham, Hackney, Shoreditch, Stepney, Poplar, and Deptford. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 125, 166, and 225 at the end of the three preceding months, had further risen to 292 at the end of September; the weekly admissions averaged 50, against 25, 29, and 42 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, St. Pancras, Hackney, Finsbury, Stepney, Southwark, and Deptford. The 19 cases of puerperal fever included three in Islington, three in Lambeth, three in Wandsworth, two in Paddington, and two in Hackney.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various metropolitan boroughs in which the deceased persons had previously resided. During the four weeks ending Sept. 28th, the deaths of 5381 persons were registered, equal to an annual rate of 15.4 per 1000, against 13.4, 16.1, and 18.5 per 1000 in the three preceding months. The lowest death-rates in the various metropolitan boroughs were 8.6 in Hampstead, 10.6 in Paddington, 12.0 in Kensington, 12.2 in Stoke Newington, 12.9 in the City of Westminster and in Woolwich, and 13.3 in Islington; the highest rates were 19.1 in Finsbury and in Stepney, 19.2 in Holborn, 19.3 in Poplar, 20.2 in Shoreditch, and 20.7 in Bethnal Green. During the four weeks of September 1047 deaths were referred to the principal zymotic diseases; of these, 24 resulted from small-pox, 58 from measles, 49 from scarlet fever, 109 from diphtheria, 62 from whooping-cough, 62 from enteric fever, and 683 from diarrhoeal diseases. The lowest death-rates from these diseases occurred last month in Kensington, Chelsea, City of Westminster, St. Marylebone, Hampstead, Wandsworth, and Woolwich; and the highest rates in Finsbury, Shoreditch, Southwark, Bermondsey, Greenwich, and Lewisham. The 24 fatal cases of small-pox largely exceeded the average and included 17 in St. Pancras, two in St. Marylebone, and one each in Hampstead, Islington, Stoke Newington, Hackney, and Southwark. The 58 deaths from measles showed a considerable decline from the average

Including membranous croup.

number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Hackney, Finsbury, Shoreditch, Bethnal Green, Southwark, and Battersea. The 49 fatal cases of scarlet fever were 19 below the average; the greatest proportional fatality from this disease occurred in Islington, Bethnal Green, Southwark, Camberwell, and Deptford. The 109 deaths from diphtheria showed a decline of 68 from the average number in the corresponding periods of the 10 preceding years; this disease showed the highest proportional fatality in St. Pancras, Islington, Hackney, Poplar, Southwark, and Greenwich. The 62 fatal cases of whooping-cough were 56 below the corrected average number; among the various metropolitan boroughs this disease was proportionally most fatal in Fulham, Stepney, Camberwell, Greenwich, and Lewisham. The 62 deaths referred to "fever" corresponded with the average number in the corresponding periods of the 10 preceding years; the highest "fever" death-rates occurred in Fulham, Chelsea, Shoreditch, Bermondsey, Greenwich, and Lewisham. The 683 deaths from diarrhoeal diseases were 134 in excess of the corrected average number; the proportional mortality from these diseases was highest in Finsbury, Shoreditch, Poplar, Bermondsey, Greenwich, and Lewisham. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during September almost corresponded with the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 168 per 1000. The lowest rates of infant mortality were recorded in Chelsea, City of Westminster, St. Marylebone, Stoke Newington, Hampstead, and Islington; and the highest rates in Hammersmith, City of London, Shoreditch, Stepney, Poplar, and Lewisham.

## THE SERVICES.

### IMPERIAL YEOMANRY.

In addition to the list of South African War Honours published in THE LANCET of Oct. 5th the following names should be noted:—

*To be Companions of the Distinguished Service Order:* Captain Percival Davidson, Medical Officer, 5th Battalion; Captain W. J. Naismith, Medical Officer, 6th Battalion; and Captain Ernest Hopkinson, Medical Officer, 15th Battalion.

### ARMY NURSING SERVICE.

*To have the Decoration of the Royal Red Cross:* Superintendents Miss M. Thomas, Miss S. J. Browne, Miss E. A. Dowse, Miss S. E. Webb, Miss S. E. Oram, and Miss A. Garriock; Nursing Sisters and Acting Superintendents Miss L. W. Tulloh and Miss L. M. Stewart; and Nursing Sisters Miss E. T. Noble, Miss A. S. Bond, Miss J. Hoadley, Miss M. G. Hill, Miss E. Nixon (New South Wales), Miss A. Bidsmead (South Australia), and Miss J. M. N. Williamson (New Zealand).

### ARMY NURSING SERVICE RESERVE.

*To have the Decoration of the Royal Red Cross:* Nursing Sisters Miss J. E. Skillman, Miss A. B. Smith, Miss A. B. Trew, Miss E. H. Beecher, Miss A. Knaggs, Miss J. Southwell, Miss E. McCall Anderson, Miss E. M. McCarthy, and Miss M. E. Greenham.

### ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon John Lyon has been placed on the retired list at his own request, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets. Dated Sept. 14th, 1901.

The undermentioned Fleet Surgeons have been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets:—Michael FitzGerald, C.M.G. (dated Sept. 1st, 1901), and Robert Bentham (dated Sept. 2nd, 1901).

The undermentioned qualified candidate for the Naval Medical Service has been appointed to be Surgeon in His Majesty's Fleet:—Pierce Leslie Crosbie.

The following appointments are announced:—Deputy Inspector-General T. D. Gimlette to Plymouth Hospital. Fleet Surgeons: C. W. Buchanan-Hamilton to the *St. Vincent* and E. W. Luther to the *Prince George*. Staff Surgeons: H. Meikle to the *Indefatigable*; J. Andrews

to the *Prince George*; W. Bett to the *Minerva*; P. V. Jackson to the *President* for a three months' course of hospital study; W. G. K. Barnes to the *Briton* and E. R. Dimsey, D.S.O., to the *Resolution* and to the *Formidable* on commissioning; and A. Maclean to the *Pembroke* for a three months' course of hospital study. Surgeons: P. L. Crosbie to the *Duke of Wellington* for Haslar Hospital; W. B. Maurice to the *Colossus*; and R. W. Stanistreet to the *Trafalgar*.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel T. F. MacNeece has been transferred to the medical charge of the Station Hospital at Nowshera. Captain C. Dalton, invalided home from South Africa after being dangerously wounded, has gone to Sierra Leone at his own request for a second tour of service in West Africa and has been posted to the Station Hospital, Tower Hill. Lieutenant M. G. Stirling is posted to the Dépôt, Aldershot. Lieutenant S. Mason has embarked for South Africa. Lieutenant-Colonel H. H. Stokes, Senior Medical Officer at the Curragh, will, on retirement, be retained in his present post as a retired officer temporarily employed. Captain Mansfield assumes medical charge of the Royal Field Artillery, Mounted Infantry, Royal Engineers, District Staff, and details, Marlborough Lines, Aldershot. Lieutenant J. H. McGregor has embarked for Barbados.

### INDIAN MEDICAL SERVICE.

Lieutenant-Colonel William Allason Simmonds, Bengal Establishment, and Lieutenant-Colonel Charles Adams-Madras Establishment, have been transferred to the half-pay list.

### VOLUNTEER CORPS.

*Rifle:* 1st Volunteer Battalion the Queen's (Royal West Surrey Regiment): Surgeon-Lieutenant J. Wayte to be Surgeon-Captain. 4th (Perthshire) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain C. W. Howatson resigns his commission.

### VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies:—Surgeon-Lieutenant-Colonel Bruce Goff, retired, late 2nd Volunteer Battalion Scottish Rifles, to be Honorary Surgeon-Colonel on appointment as Honorary Commandant. Surgeon-Lieutenant R. T. Halliday to be Surgeon-Captain; John Wright to be Surgeon-Lieutenant.

### SOUTH AFRICAN WAR NOTES.

The following have been discharged from hospital to duty:—Lieutenant F. Ashe, R.A.M.C., Major M. Kelly, R.A.M.C., and Lieutenant W. H. Odum, R.A.M.C.

Civil Surgeons C. L. Dunne, J. C. Caldwell, J. H. Stuart, and S. H. Clarke are returning home in the steamship *Victorian*.

Colonel W. L. Gubbins, R.A.M.C., and Civil Surgeons W. Faull and H. M. Roberts are returning home in the steamship *Bavarian*.

The following are also on passage home:—Major W. Hallaran, R.A.M.C.; Civil Surgeons G. A. C. Casalis (?) and D. G. MacArthur; Lieutenant-Colonel R. Vandeleur-Kelly, New South Wales M.S.C.; Major W. B. Nisbet, Queensland M.S.C.; also Captain N. Marden and Civil Surgeons Dunn, Simpson, Lowe, Brew, and Collins in the *Nubia*.

Among the casualties reported in the action in which Colonel Kekewich was recently engaged appears the name of Surgeon-Captain Kid (?), R.A.M.C., who was wounded in the left hip. He is not in danger.

### SOUTH AFRICAN AFFAIRS.

There seems to be little or no change in the military situation. From the last official summary of casualties and losses in the field force in South Africa we gather that the total casualties from all causes reported during the month of September amount to 98 officers and 2710 men, of whom, however, nearly 2000 have been sent home as invalids. Since the beginning of the war the total losses amount to some 75,000 men, but this includes all those invalided home, large numbers of whom have since rejoined their regiments in South Africa. The number of those who have died, or have been discharged the service as unfit, or have been reported missing since the beginning of the war amounts to over 22,000 men, of whom some 17,500 have actually died. Considering the time the campaign has lasted (two years), the constant fighting, and the large size of the force in the field, these losses may not perhaps, from a statistical standpoint, be regarded as heavy, especially when compared with those of other important campaigns in Europe and America. But

it must be admitted that the sacrifice of life and money entailed by the conflict in South Africa has nevertheless been deplorable. It is a poor sort of consolation perhaps, but we are glad to notice that the deaths from disease among officers and men in South Africa reported during the past month only amount to 142, as compared with 241 who have either been killed in action or have died from their wounds.

#### MR BURDETT-COUTTS AND THE ARMY MEDICAL SERVICES.

Mr. Burdett-Coutts has made a long and vigorous onslaught in the daily press on the new reform scheme for the Army Medical Services, a title which he regards as the most egregious misnomer of all that this war has produced. If the country is deluded into the belief that the Army Medical Service has been reformed, is it not, he asks, adding one more to the many dangerous shams from which we have already suffered so terribly, and which, if not unmasked, will assuredly bring new and worse disaster? He has apparently no misgivings as to the absolute correctness of his own views and statements and uncommonly little tolerance of those of other people. He does not spare anyone, civil or military, and least of all the Secretary of State for War, on whom he first and foremost casts the blame for having drawn up and laid before the Committee a scheme which he has raked with the fire of his criticism through several columns of his published communication. We have not questioned his sincerity and no one who has read his contributions to the controversy about the South African hospitals can doubt the heat and vehemence with which he has thrown himself into it. We are not particularly concerned to defend the report of Mr. Brodrick's Committee, but it is surely not open to reproach because it does not provide for every possible contingency that may arise hereafter. Mr. Burdett-Coutts has written, it must be admitted, many bitter things about the Army Medical Service in the course of this controversy and he has emphatically pronounced his judgment on several matters as if these did not admit of any doubt or were not susceptible of any other interpretation than such as he chooses to put upon them.

#### IMPERIAL YEOMANRY HOSPITALS.

The Imperial Yeomanry Hospital at Pretoria was transferred on Sept. 30th to the military authorities, and Lieutenant-Colonel Kilkelly, C.M.G., Grenadier Guards, the medical staff, and the nurses and orderlies (who were not then sailing for England) were transferred to the Imperial Yeomanry Hospital at Elandsfontein, where 294 patients, including nine officers had been under treatment. At the date of transferring the Pretoria Hospital 5227 in-patients, including 466 officers, and 1095 out-patients had been treated in that section of the Imperial Yeomanry hospitals, and 77 officers had been under the care of its medical staff in the Chesham Convalescent Home at Johannesburg opened by the Imperial Yeomanry Hospitals Committee. This is in addition to 5000 patients treated by the Imperial Yeomanry Field Hospital and Bearer Company, 6093 patients treated in the Imperial Yeomanry Hospital at Deelfontein, and 1066 at MacKenzie's Farm Branch, 19,852 patients have been treated at the Imperial Yeomanry hospitals up to Sept. 30th.

Dr. Rolleston and the other members of the Imperial Yeomanry hospitals, whose services are not required at Elandsfontein, are returning home in Government transports and hospital ships, and are expected at Southampton during the present month.

#### THE LATE AMIR OF AFGHANISTAN.

The death of the Afghan Amir has been officially confirmed. The news, which could not have been altogether unexpected, for the Amir had of late frequently suffered from gout complicated with other ailments, has nevertheless come at an inopportune moment. The Amir became seriously ill on Sept. 28th and he died at an early hour on the morning of Oct. 3rd last. It is regarded as almost certain that his son Habibullah Khan—who is at Cabul and is a man of ability and has already been entrusted by his late father with the functions of government—will succeed him. The officers of the Army Medical Services, one way and another, have had in the past a good deal of experience of field service in Afghanistan. The relations between the Indian Government and the late Amir, who was an able man of statesmanlike character and determined will, were very amicable and there is every prospect, it is believed, of these relations being continued if his eldest son and heir holds the reins of power.

#### DEATHS IN THE SERVICES.

Major John Keatly, R.A.M.C., suddenly at Bombay on

Sept. 6th, aged 41 years, from ptomaine poisoning. He was in charge of the station hospital at Kasauli, and assisted Major Semple in the administration of the Pasteur Institute which was established there in the summer of 1900. Major Keatly was selected for Kasauli on account of his special surgical knowledge. He was attached to the Oxfordshire Light Infantry in the Frontier campaigns of 1897.

Surgeon-Major-General W. A. Thomson, A.M.S. (retired), Honorary Physician to the King, aged 71 years.

Lieutenant J. B. Hall, R.A.M.C., at Harrogate. He entered the service as Lieutenant in June, 1900.

#### PRESENTATION OF WAR MEDALS.

Major-General Sir H. Trotter, K.C.V.O., commanding the home district, will present the medals on Sunday, Oct. 27th, at 1 P.M., in Wellington Barracks, to the officers, non-commissioned officers, and men of the London companies, Volunteer Medical Staff Corps, who have recently returned from active service in South Africa. Five officers and about 80 non-commissioned officers and men volunteered and were sent out with the following units: Royal Army Medical Corps, Yeomanry Field Hospital and Bearer Company, Rhodesian Field Force, and Paget's Horse. Three officers and 18 non-commissioned officers and men are still in the field.

#### THE LATE LIEUTENANT G. H. IRVINE, R.A.M.C.

A memorial tablet subscribed for by the staff of the Bristol Royal Infirmary and other friends has been placed in the chapel of that institution to the memory of Lieutenant G. H. Irvine, R.A.M.C., who was formerly a student in the infirmary and who was killed in action in South Africa in March, 1900.

## Correspondence.

"Audi alteram partem."

### "THE NEW CHIEF MEDICAL OFFICER FOR CAPE COLONY."

To the Editors of THE LANCET.

SIRS,—I am directed to inform you that an article which appears on page No. 539 of the issue of THE LANCET for August 24th, 1901, and headed "The New Chief Medical Officer for Cape Colony," has been brought to the Colonial Secretary's notice, and that while Mr. Graham is aware of the tenor of the anonymous letters which appeared in *Greater Britain*, a weekly publication which was only issued during the short period from July 22nd to August 24th last, he has advisedly disregarded them as unworthy of any serious consideration and does not contemplate entering upon a discussion of the question as therein raised. I am, however, to state that although the article which appears in your journal carefully abstains from any expression of opinion as to the correctness or otherwise of the statements made in the colonial newspaper, Mr. Graham nevertheless views with no little concern and with much regret the attitude assumed by you of implying that the allegations made in *Greater Britain* might possibly be founded on fact, a circumstance which is far from being the case. I am also to state for your information that no representation has been made to the Government which would justify the statement contained in the article in question that "the appointment has not been favourably received by the medical profession."

I am to add that Dr. Alfred John Gregory, M.D., B.S., D.P.H., &c., &c., was employed in the Health Branch of the Colonial Secretary's Department in public health and sanitation work during the period from Dec. 18th, 1891, to Dec. 1st, 1893, but without any status; that on the latter date he was appointed to the fixed establishment of the Civil Service and to the post of assistant medical officer of health for the colony, an office which he held continuously until August 1st, 1900, at which date the medical officer of health, Dr. George Turner, was detached for duty under the Transvaal Government; that Dr. Gregory was thereupon appointed to act as medical officer of health; and that at the end of February, 1901, Dr. Turner having been appointed permanently to the office of medical officer of health for the Transvaal, Dr. Gregory was then confirmed by my Government in the office of medical officer of health for this colony.

It is not the Colonial Secretary's intention to dilate upon the eminent services which have been rendered by Dr. Gregory to this colony, which, quite apart from consideration of his status in the Civil Service, have fully justified the Government in conferring upon him in recognition thereof that promotion. I am also to inform you that Dr. Gregory possesses, *inter alia*, the following qualifications—viz., Doctor of Medicine; Bachelor of Surgery; Member of the Royal College of Surgeons, England; Diploma in Public Health, Royal College of Physicians and Surgeons, England.

I am to request that you will kindly cause this communication to be published in the next issue of your journal.

I have the honour to be, Sirs,

Your obedient servant,

FRED. WHICHAM,

Assistant Under Colonial Secretary.

Colonial Secretary's Department, Cape Town, Sept. 16th, 1901.

\*\* We have great pleasure in inserting the above letter which is a satisfactory answer to the statements upon which we commented in our issue of August 24th. We then wrote as follows: "We certainly think that no one should be appointed to the position who is not hall-marked as an expert in sanitary science. Dr. Gregory may be this for all we know." We are glad to learn that Dr. Gregory has the Diploma in Public Health of the English Conjoint Board.—ED. L.

## DIFFERENTIAL DIAGNOSIS BETWEEN SMALL-POX AND CHICKEN-POX.

*To the Editors of THE LANCET.*

SIRS,—As we again have small-pox amongst us and there seems still to be a difficulty in the diagnosis between small-pox and chicken-pox, as proved by the fact that one district has insisted on the notification of chicken-pox, will you permit me to point out a well-known method by which these diseases can be easily differentiated, but which seems to be forgotten, or ignored, when we have small-pox epidemics?

The fact to which I refer is that the vesicles in chicken-pox are unilocular, whilst in small-pox they are multilocular. The practical result of this pathological fact is, that if a chicken-pox vesicle be pricked with a needle its contents can be completely evacuated and the cell will collapse, whereas in small-pox if you make 20 pricks with a needle the vesicle will not collapse, because, being multilocular, it is impossible to empty it.

I am, Sirs, yours faithfully,

GEORGE STEELE PERKINS.

Wimpole-street, W., Oct. 4th, 1901.

## TUBERCULOSIS AND HEREDITY.

*To the Editors of THE LANCET.*

SIRS,—There has come to be a strong popular impression that an inherited influence in the causation of tuberculosis has been disproved by the discovery of its dependence on organisms received from without. The belief is apparently due to some sweeping unqualified statements which have been made that we must discard the idea of actual inheritance of the disease. This, of course, is true, but the facts still remain which have led to the belief that an inherited condition influences the occurrence of the disease. These facts are equally explained by the assumption that that which is inherited or transmitted is a relatively low power of destroying the tubercular organisms which have found entrance into the system. I think that the facts not only remain but retain their significance, even when all allowance is made for the effect of infection from one member of a family to another. Indeed, such relative disability enables us to understand the greater influence of exposure to infection in some families than in others. Moreover, we must assume an analogous acquired disability in order to understand the way in which tuberculosis is a special sequel to some acute diseases or may follow grave deterioration of general health.

The question is important in regard to life insurance. It is said that some offices have ceased to take cognisance of a family history of tubercle in consequence of the widespread impression above mentioned—that an hereditary influence has disappeared from the medical creed. The change seems, however, scarcely credible, since the customary practice is based upon definite experience, on facts which may have to

be differently explained but cannot be destroyed by the new knowledge.

The question is also of importance from a practical point of view. If such relative disability may be inherited the members of such families should secure, as far as possible, occupations that involve an open-air life, in order to reinforce the power that is deficient.

I am, Sirs, yours faithfully,

Queen Anne-street, W., Oct. 7th, 1901. WILLIAM R. GOWERS.

## THE TREATMENT OF TUBERCULOSIS.

*To the Editors of THE LANCET.*

SIRS,—Much has been written the last few weeks on the important subject of tuberculosis. I have quite recently read six very clear and instructive addresses on the Treatment of Pulmonary Consumption by Hygiene, Climate, and Medicine, by Dr. J. H. Bennett, which appeared in THE LANCET in September, October, and November, 1896. Dr. Bennett says that phthisis is a curable disease—indeed, in the early stage a very curable disease—under proper treatment. His views and opinions are so precisely similar to those promulgated at the present day that I could not refrain calling the attention of my medical brethren to the fact that, although 35 years have passed, we had gentlemen at that date in our profession who were as much enlightened in the treatment of phthisis as we are at the present time.

I am, Sirs, yours faithfully,

Abingdon, Oct. 4th, 1901.

S. I. BAKER.

## SANITATION IN WEST AFRICA.

*To the Editors of THE LANCET.*

SIRS,—In these days of many theories, some sound and others extremely speculative, the question of their practical application has to a regrettable extent been lost sight of in many instances, and has been exceptionally so in the important question of West African sanitation. All honour is due to the many workers in the field of malarial research, but unfortunately the methods of prophylaxis recommended, though excellent in theory, are in most cases impossible of execution. In laying down rules for the prevention of malaria, it appears to have been forgotten that in many parts of the coast the mosquitoes bite freely in the daytime, and also that as the sun rises at 6 A.M. and sets at 6 P.M. all the year round, everyone would have to go into his house and to remain there for 12 hours out of the 24, if the rules were carried out. For the sake of illustration, suppose the gnats at home were infected and were as plentiful as they are out here. What would be thought of a sanitary scheme which involved everybody in England staying in his house from six in the evening to six in the morning? Besides this, the nature of the country, the thousands of natives (who have practically all suffered from malaria), the small number of whites, the fact that these have their work to do—which is just as hard and takes up as much of their time as in England or more—and the expense which would be incurred in their execution, place many of these suggestions outside the bounds of practical utility. Short of carrying out these schemes in their entirety, the following fundamental sanitary principles based on practical experience should, in my opinion, be laid down.

No native huts should be allowed within half a mile of European bungalows, with the exception of the servants' quarters, which should be placed to leeward and as far away as convenient, and the servants themselves should be dosed regularly with quinine under European supervision. All Europeans should take quinine regularly. Mosquito-nets should always be used; if there are no mosquitoes, the nets keep out the damp, and though one cannot help being bitten, safety for eight hours out of the 24 is worth trying for.

The houses should be built broadside to the prevailing breeze which blows almost constantly every afternoon throughout the year from the sea. They should be so constructed that by opening the doors and windows every nook and cranny could be flushed out for an hour or two every day by the wind and the mosquitoes which lurk in quiet corners swept out. No house should be more than one room deep; this is essential for complete through ventilation. They should not be too large—a two-man bungalow should be the extreme, as the greater the number of Europeans who live under one roof the greater the number of natives who go in and out and the greater the risk of those mosquitoes which hang about the house in spite of all precautions becoming

infected. There should be a verandah at least 10 feet wide to protect the walls from the sun and rain. And lastly, all houses should be raised on piles, and a layer of concrete should be put over the whole site. Thick bush and long grass should be kept down in the neighbourhood of the house and the ground should be drained and levelled.

Were the above rules carried out I am convinced that the number of cases of malarial fever would be far fewer. The water-supply can be obtained by storing rainwater collected from the roofs in large tanks; these should be thoroughly cleaned out and lime-washed at least every six months. The disposal of excreta is best effected by Moule's earth-closets; old kerosine or paint drums make excellent pans, which should be emptied daily. Where anopheles pools are found they should be filled up or drained if labour is available, at any rate those in the immediate vicinity of the house. In conclusion, I may add that even if malaria can be stamped out West Africa, owing to the peculiarities of its climate, will still remain a part of the world where the white man can only live for a year or two at a time and then will have to go to a temperate climate to recruit, before he can again resume his duties on "the coast."

I am, Sirs, yours faithfully,

S. W. THOMPSTONE, F.R.C.S. Edin., D.P.H. Camb.  
Old Calabar, West Africa, August 29th, 1901.

## "WORKHOUSE NURSING."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Oct. 5th, p. 940, Dr. F. S. Toogood makes the following extraordinary charge against me. He says: "Through the courtesy of Miss Louisa Twining I have been able to confirm that which I had previously suspected—viz., that Mr. F. R. Humphreys has annexed and labeled as 'my (Mr. Humphreys's) scheme' the plan formulated by Miss Twining and published by her in July, 1901." Your correspondent has discovered a mare's nest and his imagination has supplied the necessary local colour. There is not the slightest connexion between my scheme and that of Miss Twining, and it is absolutely incredible that Miss Twining could have led Dr. Toogood to think so.

I have before me as I write a printed form dated Sept. 23rd, 1901, from the editor of one of the great monthly magazines in which the editor says that he "will have much pleasure in giving his earliest consideration to the article kindly proposed to him by Miss Louisa Twining on Nursing in Poor-law Infirmaries by Dr. Humphreys." No one would give an introduction to another person for the purpose of assisting him to publish an article which he has been robbed of. I must therefore call upon Dr. Toogood at once unconditionally to withdraw his charge against me, and in order to afford him an opportunity of so doing I am sending him a copy of this letter in a registered envelope. I am also sending a copy to Miss Twining.

In his previous letter he made a charge against the Workhouse Infirmary Nursing Association which I asked him to withdraw. He has neither done this nor substantiated his statements and he adds to his flagrant conduct by making fresh assertions in his last letter. Let him withdraw his charges against the association or substantiate them.

I am, Sirs, yours faithfully,

Fellowes-road, N.W., Oct. 6th, 1901.

F. R. HUMPHREYS.

To the Editors of THE LANCET.

SIRS,—I am not going to enter upon a literary controversy, but my attention having been drawn to a letter from Dr. F. S. Toogood in which I am concerned, I must ask you to allow me to say that in writing to him I merely expressed my satisfaction on finding that Mr. F. R. Humphreys was advocating the plan which I had so often suggested for the amalgamation of the sick in central workhouses, which I considered the only remedy in the case of the small country ones. It cannot be of the slightest importance to anyone to know who first started the idea and I regret to see such a question named. Having worked with the association for 22 years, may I add my conviction that all the accusations made against it are absolutely unfounded?

I am, Sirs, yours faithfully,

Oct. 7th, 1901.

LOUISA TWINING.

## "THE ELECTROLYTIC TRANSMISSION OF SULPHUR."

To the Editors of THE LANCET.

SIRS,—In reply to Dr. Longridge's letter of Sept. 28th I consider that he is wandering from the subject altogether. My "discovery" applies only to the Harrogate sulphur waters, and if he can prove that anyone else made it before me I am willing to drop the word. Till then I stand by my guns.

I am, Sirs, yours faithfully,

Harrogate.

FRANCIS WM. SMITH.

## A MEDICO-LEGAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—I venture to suggest the formation of a medico-legal society, the chief object of which should be the discussion of questions of a legal character arising in every branch of medical work. No doubt there are many teachers of medical jurisprudence, medical barristers, and others willing to form such a society, the advantages of which are obvious.

I am, Sirs, yours faithfully,

Oct. 7th, 1901.

M.D., D.P.H., Barrister-at-Law.

## THE GENERAL MEDICAL COUNCIL AND REGISTRATION.

To the Editors of THE LANCET.

SIRS,—Allow me to submit a case in illustration of the hardship of the present regulations, or want of regulations, of the General Medical Council on the registration of students commencing their course of medical study. My son is studying at a large public school which provides a course of study in science, especially arranged for the preliminary scientific (M.B.) and intermediate science examinations at London University. The school is accordingly recognised by the Conjoint Board of the Royal Colleges of Physicians and Surgeons for the commencement of professional study. Having passed his matriculation examination my son has entered on the science course at this school, but his application to the General Medical Council to be registered is refused on the ground that the school, though recognised by the licensing bodies, has not been approved by the Council. It seems, therefore, that the result of the want of understanding at present painfully evident between the Council and these bodies is to inflict grave hardship and injury upon individual students who may be deprived of a year's counting in their curriculum. Nor is it easy to ascertain what institutions are at the present time approved by the Council. The election of Direct Representatives is about to take place. Can nothing be done to bring the authorities which preside over medical education into agreement on some equitable terms? They disagree; we suffer.

I am, Sirs, yours faithfully,

London, Oct. 7th, 1901.

M.D., &c.

## "THE RECONSTITUTION OF THE ROYAL ARMY MEDICAL CORPS."

To the Editors of THE LANCET.

SIRS,—With great interest I opened THE LANCET this morning to see what you thought of the War Office Committee's scheme for improvements in the Royal Army Medical Corps and it was with not a little astonishment that I read your editorial views on the subject. I think that I am but expressing the views of nine-tenths of the officers of the corps when I say that Mr. Brodrick has made an honest and sincere effort to improve the medical service of the army, but that unfortunately in this particular case he has sought advice from men who, judging from their proposals, seem to have but an imperfect idea both of the conditions under which the corps works and of the administrative difficulties inseparable from working a medical *personnel* scattered all over the world.

Within the last week I have taken the opinion of at least 40 officers of the corps on this scheme, and I can assure you that not one of them thinks it other than unworkable. The only bright spots in the proposals are the granting of adequate rates of pay and the simplification of the entrance examination. The great blots on the scheme are the abrogation of the right to retire after 20 years' service on £1 a day; the failure to make the Advisory Board one which

can enforce its recommendations and not merely advise and supervise; the omission to lay down any minimum strength of officers and men for the corps; and the absolutely ludicrous system of periodical examinations. These latter, to my mind, constitute the worst feature of the scheme, for they indicate a system of distrust of the individual and the establishment of a series of inquisitorial tests only calculated to develop a class of book-worms and men well based in laboratory experiments and technique, but devoid of those clinical and manly attributes which are essential for the making of a good soldier-doctor. With the institution of these recurring examinations and periodical attendances at certain hospitals, it will be interesting to know how and by whom the foreign service is to be done, and how rosters for such service are ever to be kept. Much as I want to see the corps placed upon a sound footing, and, moreover, flourishing both in numbers and reputation, I fear that such will never be secured by any such *dilettante* and academic methods as are now proposed. And, what is more, I feel sure that no men worth having in the corps will ever consent to enter it on terms of such precarious tenure as are now offered to them in this tentative scheme. The more one reads the scheme and thinks over it the more one marvels how the 13 intelligent men who composed the Committee can have seriously put it forward as a remedy for the existing state of things. They seem to have lost sight of the fact that they are not legislating for students but for men as old as, and in some cases older than, themselves. The corps is full now of men eager to work and perfect themselves in their profession, but only lacking the opportunities owing to excess of foreign service and inability to obtain leisure leave. The *personnel* of the corps is right enough; it only needs an increased establishment to ease the pressure. The granting of adequate pay alone will do that and the rest will follow.

THE LANCET is an influential journal and it is much to be regretted if its editorial views fail to be in touch with the great mass of professional opinion. Certainly, in this particular case I think that a further examination of the scheme will suggest a modification of your expressed approval.

I am, Sirs, yours faithfully,

IMMUNE.

Oct. 5th, 1901.

\* \* We simply stated the general effect of first impressions which we received from a perusal of the report, and we said that the recommendations were in the nature of an experiment. The scheme is but a scheme and can be modified.—  
ED. L.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Henshaw's Blind Asylum.*

ARCHDEACON WILSON'S strictures on the care of the blind at Henshaw's Asylum drew forth a long defence of the institution in the *Manchester Guardian* of Oct. 4th, and on the 7th there was another letter from Archdeacon Wilson in which he made specific statements which show that there are many matters as to which improvement is desirable. It seems that when a surprise visit was made by His Majesty's Inspector he found "the state of the building unsatisfactory in point of cleanliness," which Archdeacon Wilson more than confirms from his own observation. The latter mentions "uncleanly arrangements for washing" and the "condition of the closets," as to which "details might be added which would be not only distasteful but disgusting." Supervision may also be improved if, as is stated, somewhere about 40 blind boys in one dormitory are supervised by a "blind man sleeping in an adjoining apartment," which is said to have been the case a month ago. "A sick-room of four girls, two of whom were very ill," was in charge "of a nearly blind woman who could not perceive how dirty the beds were." Various other points were mentioned. The food seems to be sufficient and of good quality, but when Archdeacon Wilson was there no knives and forks were in use, but only spoons, and "the result was that all were fed on minced meat," and he adds, "think of the awful sameness." Other matters, as education, work for the blind, &c., are touched on which seem to be in need of revision, but those mentioned above are important in their relation to health and morals. It appears that there are no women on the committee,

although the statements as to the girls' sick-room and the picture of the comfortless sitting-rooms and of "the poor old women sitting silent on the hard benches," show that there is room at the asylum for the sensible but sympathetic work of educated women. The meetings of the committee are probably occupied chiefly with the business matters of the institution, so that with no "wilful neglect or breach of trust" they may be open to the charge which Archdeacon Wilson makes of lack of observation, of special knowledge, "and it may be lack of control of their officials." Let it be hoped that the prominence now given to the asylum will result in improved treatment of the blind and the increased prosperity of the institution.

### *Less Cubic Space for Lascars than for Whites.*

At a meeting of the Manchester Port Sanitary Authority held on Oct. 7th it was reported that during the month of September 136 vessels had been examined, in 28 of which defects or insanitary conditions were found. Dr. J. Pringle, the medical officer, had inquired into a case of overcrowding on a vessel carrying a Lascar crew. In one compartment of the fore-castle certified to carry 14 white men there were 16 Lascars, and in another certified for two white men there were four Lascars. The captain stated that the cubic space and floor area which were required by the Indian Government were provided. The boat originally carried a white crew and it seems that 16 Lascars are considered equal to 12 whites, and in this case 20 had the accommodation for 16 whites. It is said that the Board of Trade standard of accommodation for white men of 72 cubic feet, which is not over liberal, did not apply to Lascars. The latter are presumably employed for the sake of economy, but it is scarcely to be expected that the overcrowding of coloured men will increase their efficiency or tend to the true economy which is promoted by health and vigour.

### *Salford Cottage Homes.*

Salford is making provision for her pauper children away from the injurious influences and associations of the workhouse. The foundation-stone of cottage homes for children was laid on Sept. 19th at Culcheth, in the open country, where 45 acres of land were bought for £4500. The estimated cost of the work when completed is £63,711. There are to be 11 semi-detached homes for 12 children each, with rooms for the foster-mother, and two single homes accommodating 12 each. There will be an infants' school and a mixed school to accommodate 399 boys, girls, and infants, and a hospital for 16 children and the requisite staff. There will also be playgrounds, and the elder boys will be taught trades and the girls sewing and housework. The plans have been arranged to admit of extension. The work is to be completed in two years. At a tea given after the ceremony Mr. W. Moorsom, assistant inspector of the Local Government Board, spoke of the gratification he had felt at the condition of the children at the Chorlton Board's Styal Cottage Homes. He also spoke with equal approval of the "non-poor-law homes" established by the Wesleyan body at Edgeworth. Mr. Alderman Mainwaring, chairman of the Chorlton Board, said that "he had come to the conclusion that pauperism was not hereditary." No doubt the children of paupers became paupers from infection, if the term may be so applied, as phthisis is often passed from parent to child, and the tendency for the children to drift to the workhouse, as was the rule in the old days, will be checked if only they are preserved from its associations during childhood.

### *Infectious Diseases Hospital for Preston.*

At the meeting of the Preston Town Council on Sept. 26th a motion was passed in favour of the erection, at a capital outlay of £20,000, of an infectious diseases hospital. From January to Sept. 24th, in addition to cases of typhoid fever, diphtheria, erysipelas, and other infectious diseases, the Health Committee had had to deal with 1448 cases of scarlet fever. In the discussion on the proposal Dr. Browne said that every year typhoid fever was present in the town; every winter there was a certain amount of diphtheria, while scarlet fever, seldom absent, returned every three or four years with renewed vigour. "If the members of the council could go with him on his rounds and see the results accruing from non-isolated cases he was positive that not a single objection to the expenditure would be forthcoming."

### *The Drought.*

There was a heavy rainfall on Oct. 5th and 6th on the Longdendale gathering grounds, which augmented the stock

of water in hand by 141,000,000 gallons and raised the estimated supply from 21 days to 25 days. It seems as if the drought were coming to an end at last, but the same has been said before only to be falsified by the event. There is abundance of water in Thirlmere, but the quantity supplied must remain as it is till more pipes are laid.

Oct. 8th.

(FROM OUR OWN CORRESPONDENTS.)

### *Conferences on Tuberculosis at Cardiff and Swansea.*

THE Mayor of Cardiff began his year of office by setting before his fellow-townsmen the special claims of the Cardiff Infirmary and by successfully wiping out within a few months a debt upon the institution of £12,000, and he has made the closing weeks of his official year memorable by convening a conference to discuss the question of the prevention of tuberculosis. This conference, which met at the Town Hall, Cardiff, on Oct. 3rd, was a most representative gathering of men from every part of South Wales and Monmouthshire, about 500 persons being present. Lord lieutenants, high sheriffs, mayors, chairmen of county councils and of district councils, delegates from sanitary authorities, medical officers of health, and a large number of medical practitioners responded to the mayor's invitation. The meeting was addressed by Dr. Isambard Owen and Dr. Alfred Hillier, after which the following motion of Sir John T. D. Llewelyn and Dr. C. T. Vachell was unanimously carried:—

Dr. Isambard Owen and Dr. Alfred Hillier as representing the Central Committee, having explained the object of the Association it is resolved that a branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis for South Wales and Monmouthshire be and is hereby formed.

Subsequent resolutions elected Lord Windsor (the Lord Lieutenant of Glamorganshire) as president, various ladies and gentlemen as vice-presidents, a treasurer, Dr. Eldon Pratt of Cardiff as secretary, and a large executive committee (the members of which include the presidents of the local medical societies and of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health). The executive committee were empowered to collect subscriptions, to obtain approved public lecturers, to diffuse literature relating to the prevention of tuberculosis, and to promote the establishment on a partially self-supporting basis of open-air sanatoria for tuberculous patients. The subscription to the branch was fixed at 5s. per annum. At the close of the meeting Dr. W. G. Savage gave at the Cardiff and County Public Health Laboratory a very interesting description with the aid of lantern slides of some of the principal continental and British sanatoria. On Oct. 4th Dr. Isambard Owen addressed a large meeting at Swansea, when it was decided to establish an auxiliary branch to the South Wales and Monmouthshire branch created at Cardiff on the previous day. It was very noticeable both at the Cardiff and the Swansea meetings that the speakers lay and medical urged the importance of notification of cases of phthisis to the medical officer of health. The chairman of the Monmouthshire County Council (Alderman E. Grove) advised not only compulsory notification but also compulsory removal of phthisical patients to rate-aided sanatoria. The Health Committee of the Cardiff Corporation have for some time been active in the direction of the prevention of tuberculosis. About two years ago the medical officer of health (Dr. E. Walford) issued not only a general circular on the subject, but a memorandum was also sent to medical practitioners in the town offering free bacteriological examination of sputum and asking for voluntary notification of tuberculous cases coming under their care; a circular was at the same time sent to all purveyors of milk and cowkeepers pointing out their obligations under the Dairies, Cowsheds, and Milkshops Order of 1899 and offering the free application of the tuberculin test. In the year 1900 there were 322 deaths in Cardiff from various forms of tuberculosis, and in 84 cases disinfection was carried out by the sanitary authority at the request of medical practitioners or of relatives of the deceased person. There are no placards with regard to spitting distributed in Cardiff, but for several years past in the free libraries and museum of the town there has been prominently displayed the following notice: "The reading-room attendant has been instructed by the committee to expel from the building any person found spitting."

### *Llangyfelach Rural District.*

Mr. F. T. Bircham, general inspector of the Local Government Board for Wales and Monmouthshire, does not confine himself to Poor-law administration, but has recently been attending the meetings of some sanitary authorities in his district to whose notice he has brought some of their shortcomings. On Oct. 1st he told the Llangyfelach Rural District Council that the Local Government Board must have some definite promise that the council was providing an adequate water-supply for the district, sewerage schemes in particular parts of the district, and an isolation hospital. The chairman of the council protested that the authority was doing its duty in these matters, because drainage schemes should be preceded by an adequate supply of water, and that an arrangement had been made to obtain this supply from the Swansea Corporation upon completion of the new water-works in five or six years' time.

### *Bridgend Workhouse.*

The need of increased accommodation at the Bridgend Workhouse has been frequently during the last few years urged upon the board of guardians by the Local Government Board. In July last when a definite proposal to carry out the extensions was made it was defeated by a motion to defer the work for twelve months. Since then it has been decided to carry out a very small portion of the extensions by erecting a kitchen and laundry. As one of the most urgent needs of the institution is the provision of an infirmary, which it is estimated will cost about £5000, the Local Government Board will only sanction a loan for the erection of the kitchen, &c., on condition that the infirmary is also proceeded with very shortly.

### *Home for Consumptives at Bristol.*

At the meeting of the Bristol Board of Guardians held on Oct. 4th several members spoke very strongly on the necessity for procuring a site near Bristol and at once erecting suitable buildings both for the treatment of acute cases of phthisis and for patients in the early stages of the disease. In the meantime it was decided to continue the arrangement with the North London Hospital for Consumption at Hampstead whereby two beds in this institution are at the disposal of the board for a yearly payment of £105.

### *Devonport Infectious Hospital.*

At an inquest held at Devonport on Oct. 4th upon a child who had died in the Infectious Hospital it was stated that there was no mortuary in the hospital, a nurses' bathroom being used for that purpose. The coroner said that many schemes had come before the borough council for the enlargement of the hospital, and doubtless when the building was enlarged a mortuary would be provided.

Oct. 7th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The late Bailie Pollard of Edinburgh.*

I REGRET to have to announce the death of Bailie Pollard, whose name was a household one in connexion with all matters bearing upon the public health and the sanitation of the city of Edinburgh. For close on 20 years Mr. Pollard had been connected in one or other capacity with municipal works in Edinburgh. In 1891 he became convener of the Public Health Committee of the Town Council in succession to Sir James Russell, and in 1894 he was elected a Bailie. As convener of the Public Health Committee Mr. Pollard's work was most important and deserves full recognition. He was an enthusiastic worker in the region of public health and spared no pains to make his knowledge of the subject as complete as possible. Mr. Pollard paid several visits to Germany in order to study the municipal institutions of that country. He was especially interested in the welfare of the fever hospital and its patients, and during the whole time that he was convener of the Public Health Committee he paid when in town a weekly visit to the hospital when he saw practically every patient in the house. He in this way became personally acquainted with every member of the medical and nursing staff of the hospital. He and his wife also took an interest in the wives and families of the men of the poorer class whom he came across in the hospital, visiting them in their own homes and doing all he could

to help them. Mr. Pollard threw all his energies into the scheme for building a new fever hospital at Colinton Mains. He, together with the city superintendent, travelled over a large part of Europe in order to become familiar with the latest improvements in hospital construction, so that the new hospital might be as suitably constructed and well-equipped as possible. The formal opening of the hospital was to have taken place in the summer, but was put off on account of Mr. Pollard's illness, and he has not lived to see the full completion of the work. During the last few years Mr. Pollard interested himself in the question of the stamping out of tuberculosis and he had suggested that when the new fever hospital was opened a portion of the old building in Infirmary-street might be set apart for the use of persons in the last stage of consumption and therefore sources of danger to the community. Mr. Pollard is survived by a widow and three young daughters. The funeral took place on Sept. 28th, and was attended by a large and representative gathering of citizens of all classes. Mr. Pollard was held in the highest respect and esteem both for his own and for his work's sake.

#### *The New Edinburgh City Hospital.*

The new City Hospital, in the construction of which the late Baillie Pollard was so keenly interested, is not yet ready for occupation, although the external fabric has been practically completed. The selection and insertion of the internal fittings cannot be done hastily in view of the demands of modern medicine, so that at least a year will elapse before the structure is ready for occupation.

#### *Glasgow University.*

At the meeting of the Glasgow University Court on Oct. 3rd Professor John Young intimated that on the recommendation of his medical advisers he had determined to ask permission to retire from the chair of Zoology which he has occupied for the long period of 35 years. In making this announcement Professor Young stated that he did so with great regret, but that the state of his health compelled him to take this step in the interests both of himself and of the university. While resigning his chair he hoped to be able to retain his position as keeper of the Hunterian Museum and to discharge all the responsibilities of that office. On behalf of the court Principal Story and Sir John Neilson Cuthbertson expressed profound regret at the prospect of Professor Young's withdrawal and trusted that the university would long enjoy the advantages of his services in connexion with the museum to which he had given so many years of earnest and ungrudging labour. In addition to the chair of Zoology, Professor Young has held for many years the Honeyman-Gillespie lectureship on Geology founded in 1876. He has been an ardent advocate of the proposal to erect this lectureship into a separate chair, but hitherto want of funds has made this impossible. It is probable that the present vacancy will be utilised to separate the two appointments. The patronage of the vacant chair is in the hands of the Crown. The income is about £800 per annum. The following appointments have been made by the University Court: Dr. James F. Gemmill to be Lecturer in Embryology, Dr. Charles Workman Lecturer and Examiner in Pathology, Dr. John Lindsay Steven Lecturer and Examiner in Medicine and Clinical Medicine, and Dr. Magnus Maclean to be Additional Examiner in Physics for Degrees in Medicine and Science. The opening of the medical classes at the University and extra-mural schools is announced for Thursday, Oct. 17th. Ferguson scholarships of the value of £80 each per annum and tenable for two years have been awarded to William Rennie, M.A., of Edinburgh University, and to David Macfarlane Stewart, M.A., and Alexander Dunlop Lindsay, M.A., both of Glasgow University.

#### *Port Sanitary Authority for the Clyde.*

The recent outbreak of bubonic plague in Glasgow, followed as it was by an epidemic of small-pox, has caused the sanitary authorities to search for the weak points in their armour. One of these, it is urged, is the want of effective medical control over vessels entering the port. The jurisdiction of the Glasgow health authority, of course, begins and ends at the city boundaries, and a similar statement is true of the other municipal areas which fringe the banks of the Clyde. Thus the same vessel, in being moved, for example, from one dock to another, may, even on successive days, come under the claim of different authorities. In so far as any general supervision of vessels entering the Clyde is undertaken this is effected

at Greenock, where the customs authorities board vessels and report the presence of any infectious disease to the local health officer. These arrangements are admittedly unsatisfactory, and the Glasgow Corporation, with a view to remedy them, has applied for a provisional order to create the corporation the port sanitary authority for the river. During the past week an inquiry in connexion with this application has been conducted in Glasgow before Sheriff Jameson. The witnesses called in support of the corporation have included Dr. A. K. Chalmers (medical officer of the city), Professor John Glaister, Dr. E. W. Hope (medical officer of the city and port of Liverpool), and Mr. Mackenzie (general manager of the Clyde Trust). The burghs of Greenock and Govan, and various county councils having authority in the Clyde basin, appeared by counsel to oppose the application, some of them condemning such a proposal as unnecessary and others advocating the establishment of a joint sanitary authority. After several days' hearing Sheriff Jameson intimated that he should make his report to the Board of Supervision. The result has not yet been made public.

#### *Glasgow Parish Council.*

In his annual report to the Glasgow Parish Council Mr. John Carswell deals again with the alleged increase of lunacy. The figures of his report show that the local occurrence rate has increased from 44 per 100,000 in the years 1890-95 to an average of 64.9 since that period. But the real cause of this increase, Mr. Carswell argues, is the improved administration of the Lunacy Acts and a diminution of the prejudice against pauper asylums. The report also discusses the question whether the saving of life in childhood by protection from infectious and tuberculous disease helps to increase the number of insane in adult life, and here also a negative conclusion is arrived at and supported by argument.

#### *The late Dr. James McLintock.*

The death is announced of Dr. James McLintock, who was appointed a medical member of the Local Government Board for Scotland when that body was first established, and who only retired from the Board about three years ago. Dr. McLintock has left the record of his work written in much of the public health legislation now exercising such a beneficial influence throughout the country, and in this way he has well served both his own and successive generations.

#### *Glasgow Medico-Chirurgical Society.*

The office-bearers for the session 1901-1902 are as follows: President, Dr. W. G. Dun; vice-presidents, Dr. J. Lindsay Steven and Dr. A. E. Maylard; treasurer, Dr. R. Barclay Ness; editorial secretary, Dr. Hugh McLaren; general secretary, Dr. W. K. Hunter. The first meeting of the current session was held on Oct. 4th, when the President delivered his inaugural address, his subject being Blood-letting in the Treatment of Disease.

#### *Bequests to Glasgow Hospitals.*

Under the trust disposition and will of the late Sir William Laird a sum of £10,000 is allotted for distribution among various charitable institutions in the West of Scotland. The principal legacies are: Glasgow Royal Infirmary, £2000; Western Infirmary, £1000; Victoria Infirmary, Royal Hospital for Sick Children, and Asylum for the Blind, each, £500. The Merchants' House of Glasgow and the Alexandra Hospital, Coatbridge, also each receive £1000.

Oct. 8th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Mourne Water-supply for Belfast.*

SIR ROBERT MCCONNELL, Bart., D.L. (ex-mayor of Belfast), formally opened the new service reservoir at Knockbracken on Oct. 2nd. This is situated on the Saintfield-road, about five miles from the centre of the city of Belfast; it is in water surface 17½ acres and its capacity is about 100,000,000 gallons. The object of this reservoir is twofold: it maintains a steady pressure in the district of supply and it has sufficient water in store to keep up the supply when repairs are requisite on the aqueduct. From the Kiekel river (in the Mourne mountains) to the Knockbracken reservoir the length of the aqueduct is about 35

miles. In ordinary level ground the cut-and-cover mode of construction has been followed (16 miles), through mountains tunnels have been driven (seven miles), and valleys have been crossed by means of dips formed of steel (where the pressure is greatest) and cast-iron pipes (12 miles). The longest tunnel is three and a half miles through rock and the most difficult one was made under Slieve Donard mountain, near Newcastle, two and a quarter miles through granite and indurated Silurian rock, the latter being the most obstinate to penetrate. It took three and a half years to make this tunnel. At present the water will come from the Annalong river (a temporary cut having been made from that stream), but south of that river the works of the aqueduct are incomplete. In a few months the southern part of the aqueduct will be so far complete that the Annalong river will be laid under contribution. These streams will give 10,000,000 gallons per day for seven or eight months in the year, and by using this supply in conjunction with the reservoirs on the existing works sufficient water will be provided in the summer to tide Belfast over for several years, but it is intended, also, in the future to build two reservoirs, one in the "Silent valley" of the Mourne mountains and the other in the "Annalong" valley. Up to the present £700,000 has been spent and to complete the works in hand another £100,000 will be needed. To construct the "Silent valley" reservoir £250,000 will be required, and to develop the entire scheme (in order to bring in the waters of both rivers) a further sum of £300,000 will have to be expended, so making the grand total more than one and a quarter millions of money. By spreading the expenditure over a number of years the ratepayers have felt it very slightly. When the works are complete Belfast will possess an unlimited supply of good water.

#### Fermanagh Infirmary.

On Oct. 2nd, in the Town Hall, Enniskillen, the Earl of Erne opened a bazaar to raise sufficient money to allow the necessary improvement of the infirmary to be carried out on modern lines. All classes and creeds have combined to make the sale a success. The infirmary dates back to 1765.

#### The Irish University Question.

Dr. W. A. McKeown (Senator of the Royal University of Ireland) has published in the Irish press an article which, he thinks, proves that in relation to the medical profession Irish medical schools educate far more medical men than can find occupation in Ireland. In proof of his statement he publishes two tables:—

Table showing the Distribution of Persons holding Irish Medical Qualifications according to the Medical Directory of 1900.

	Resident in Ireland.	Resident in London.	Resident in England (provincial).	Resident in Wales.	Resident in Scotland.	Resident abroad.	In the Naval, Military, and Indian Medical Service.	Total.
Graduates of the Royal University of Ireland	568	135	379	29	9	114	279	1513
Graduates of the University of Dublin	361	65	283	12	1	122	190	1034
Licenses of Irish licensing bodies	1081	201	627	43	7	303	343	2605
Total	2010	401	1289	84	17	539	812	5152

This demonstrates that the medical graduates of the Royal University are greatly in excess of those of the University of Dublin, that the number of practitioners holding Irish qualifications and resident in Ireland is 2010, and that the number of practitioners holding Irish qualifications and resident outside Ireland is 3142; but as this table does not show fully the work done by Irish medical schools, as many students holding certificates of attendance at Irish schools and hospitals go to Scotland for their final qualifications, Dr. McKeown gives another table showing the medical practitioners resident in Ireland, chiefly educated in Ireland, who have taken qualifications elsewhere. These for practical purposes may all be regarded as Irishmen. Only a few

Scotchmen or Englishmen settle in Ireland and mostly in connexion with medical schools.

Licenses of Scotch licensing bodies	370
Licenses of English licensing bodies	29
Graduates of Scotch universities	66
Graduates of English universities	4
Graduates of colonial and foreign universities	8

Total 477

Further, a great many medical students educated in Ireland take qualifications from Scotch licensing bodies but settle outside Ireland. It is impossible to give the numbers of these. Dr. McKeown submits that these tables show that no additional facilities are required to induce students to engage in study for the medical profession. Existing schools should be better equipped, but no new universities, local or sectarian, are needed. The medical schools of Cork, Galway, Dublin, and Belfast could educate two or three times the number of students who at present resort to them. Galway, according to Dr. McKeown, has only supplied 16 medical graduates in 10 years and there is, therefore, no adequate reason why it should be maintained, the results being certainly not commensurate with the cost of keeping up the medical faculty of that college.

#### The Royal University of Ireland.

The final (M.B.) examinations of the Royal University of Ireland were held last week, the results being announced on Oct. 7th. The two inspectors of the General Medical Council, Dr. D. C. M'Vail (Crown Representative for Scotland) and Sir George Duffey, were present and closely watched all the modes of examination. It will be interesting to have their report.

#### Cork Hospital Saturday Collection.

The Cork Hospital Saturday collection was held under rather unfavourable circumstances as far as the weather was concerned, and for that reason it was expected that it would be a comparative failure. However, the street collections realised nearly as much as in the previous year, and it was a great source of pleasure to the ladies to find that the really poor were so ready to contribute what they could towards the support of the hospitals. Owners of large firms had collections made amongst their employes, and from that source rather large sums were received. Last year, mainly through the instrumentality of the Lord Mayor (Sir Daniel Hegarty), hospital aid associations were established, and through their instrumentality collections were made in some of the country towns. This year the operation of those associations has been extended and it is anticipated that the result will be a substantial addition to the resources of the various city hospitals.

#### Cork North Infirmary.

Mr. Denis Murphy has been appointed pathologist to the Cork North Infirmary.

Oct. 8th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### Infant Life Protection.

A LAY newspaper has commenced a campaign against the medical department which is charged with the protection of infant life. The fight is being waged in a series of articles written by a Parisian medical practitioner and the articles have created a great sensation. They affirm that the medical inspection of sucklings is very inefficiently carried out, that infants in the country who are brought up by hired wet nurses are very rarely inspected by the medical officer in charge of the department in question, and that the excessive mortality amongst such children is due to this cause alone. Numerous letters from inspecting medical officers have appeared in the newspaper in question, none protesting against these allegations, but, on the other hand, confirming them, while they declare that the lamentable situation is due to the exceedingly faulty organisation of the department concerned. Since 1874 there has existed in France a law called the "Loi Roussel" which provides for the medical inspection of children brought up in the country by hired wet nurses and that law deals both with children of town parents who have been confided to such nurses by their parents and with the children of women who may have left the country for the town to become wet nurses in various families and who have handed over their children during the time of their service

either to their relatives or to neighbours still resident in the village. The law also provides that every woman going to a city to take a place as nurse in a family should have a certificate from the mayor of her village saying that her last child was living and had reached the age of at least seven months, or else was being brought up in the village by a woman possessed of the necessary qualifications for carrying out this duty properly. Moreover, when she reaches the city the would-be nurse is not to be entered on the register until she has undergone medical examination which must state that she is suffering from no contagious affection and that she is in a proper state of health to furnish a plentiful supply of healthy milk. The supervision of the children remaining in the village, as I have just said, is confided to medical inspectors who are obliged to visit each child at least once a month, as well as when they are summoned by the nurse in charge, but, as a matter of fact, this department, which looks exceedingly well on paper, works very badly in practice. The woman who leaves her village to become a nurse in a town has no difficulty in getting a certificate from the mayor, who hardly ever refuses one lest he should become unpopular. No certificate is required from the medical man of the village, which is the only one that could have any value. The duties of the medical inspectors are very badly carried out and the remuneration which they receive for their work is quite insufficient. They only receive one franc for their monthly visit and the patient may very likely live seven or eight kilometres away from the residence of the medical man. Thus a medical man who had 30 nurslings on his list would receive 360 francs per annum and might very likely be obliged to travel more than 1000 kilometres to see them. It may be said that no medical man is obliged to undertake such a post, but, as a matter of fact, he is obliged to do so, because, supposing he refuses, even in a very poor village where there is difficulty in gaining his livelihood the mayor does not hesitate to put out advertisements for a young medical man to take the post, and such a post is generally snapped up, for a young practitioner who is just beginning his career imagines that he may in this way lay the foundation of a practice, and thus he renders the situation of the medical man already in possession even more difficult than before. Finally, this minimum fee of one franc is only payable to the medical man for his obligatory monthly visits. Any other visits which he may make at the appeal of the nurse are supposed to be paid for by the relatives of the child, who, however, often refuse such payment. Even if the visits of the medical inspector are made regularly the reports of the medical man are not of much use, for if he states that the child is being brought up in an improper manner his report produces next to no result. He can only send in such a report to the Prefect, and it is only after two or three such reports have been received that the Prefect at length decides to send a departmental inspector to interview the nurse. Very often such inspector is not a medical man and the only thing he can do is to make remonstrances, which are passed over in silence. The medical man ought to have the right to take away any child at once from the house of a nurse who is not doing her duty properly and to place such child in a departmental *crèche* pending the time that the Prefect can or will communicate with the relatives of the child. The Prefect of Police in Paris has been stirred up to action by the reports published in the newspapers and has just issued an order, but it will probably have no result. The Prefect, who is unable to make the necessary new laws, can do nothing but insist upon the rigorous application of the existing law—that is to say, the Loi Roussel—and the only thing which the order does is to insist upon the necessity of a certificate from the mayor for any nurse who comes to seek a situation in the city. As a matter of fact the mayor never refuses such certificate, and even if it is found to be false the penalty to which the mayor could be sentenced is so severe—viz., the sentence of hard labour—that the Government would not dare to sentence one who may be a faithful public servant for such a slight matter. If such a sentence were passed, it would frighten a great many women who would simply do without the certificate of the mayor and who would come to town without taking the trouble of getting put upon the register: they would seek a situation on a simply personal recommendation, and this recommendation would be considered quite sufficient by a number of families, and so the nurse would escape altogether from the medical control

which the Prefect of Police at present exercises over those whose names are on the register. As a matter of fact it is perfectly well known that out of 22,000 persons who annually take over the charge of nurslings in the country only 4000 have any authorisation from the Prefect to do so. 18,000 nurslings are annually given over to nurses known to their parents only by a simple recommendation and are without any prefectural control. The circular sent out by the Prefect in Paris, which makes admission to the register very difficult, will do nothing except to augment the number of nurses who are anxious to escape from it. It would have been more simple and much more rational to have made it necessary for a nurse to obtain, in place of the certificate of the mayor, a certificate from the local medical man, who is in a position to judge of the condition of health in which the nurse is. Such a medical man would be conscious of his responsibility and would have an interest in seeing that later the nurse brought up the child entrusted to her care in a proper manner so that his certificate would be justified.

#### *Unveiling of a Memorial to Pasteur.*

On Sept. 29th a memorial was unveiled to the memory of Pasteur at Arbois, his home. The memorial is the work of Monsieur Daillon, the sculptor, and Pasteur is represented seated. On the other side of the pedestal, which is severe in style, are two bas-reliefs representing respectively a group of vine-dressers and herdsmen, symbolising the services which Pasteur rendered to agriculture, and the other showing the operation of inoculation for hydrophobia. On the plinth is a medallion containing the effigies of the father and mother of Pasteur. The Minister of the Colonies, who presided at the ceremony of unveiling, finished his oration by saying that if throughout the world there is one popular Frenchman that one is Pasteur.

Oct. 7th.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

#### *The Plague at Naples.*

THE official bulletins in regard to the plague at Naples show that no serious extension of the outbreak has yet occurred. On the evening of Oct. 5th no fresh case had been reported in the city for 10 days and it was expected that on the 6th Naples would be officially declared free from the disease. Many suspected cases, indeed, have been reported to the authorities both from the city itself and from the neighbouring centres of population, but with the exception of one case at San Giovanni a Teduccio (which was immediately isolated) none of these cases have proved to be plague. At present there are seven cases at Nisida actually under treatment, and 135 "contacts," the latter being in good health except one girl who has a rise of temperature and is being carefully watched. Several false alarms have also been sounded at Rome, but fortunately all have turned out to be entirely baseless. The task of disinfection at Punto Franco, the locality where the first cases were discovered, has proved a most difficult one to carry out effectually, on account of the legal questions as to compensation and the powers conferred by law upon the sanitary authorities to which it has given rise. The value of the merchandise, consisting chiefly of skins, bales of cotton, and grain, accumulated in the stores there amounts to many millions of francs, and the authorities are still apparently undecided whether the whole should not be destroyed. Meanwhile, the loss to Naples from stagnation of its commerce alone must have been immense, and the consequent misery amongst the poorer classes very great. The rag-dealers, for instance, who have been prohibited from practising their calling, are in dire straits and have had to appeal to the Government for relief. On the whole, however, the situation is not regarded as very serious and the most competent authorities, such as Professor Gualdi of Rome, consider that all danger is now practically at an end. Whether this optimistic view is justified must very soon be tested by events, the incubation period of plague being comparatively short and the diagnosis, once suspicion is aroused, not difficult.

Oct. 6th.

## Medical News.

**SOCIETY OF APOTHECARIES OF LONDON**—At the Primary Examination the following candidates passed in the subjects indicated:—

### PART I.

*Biology*.—J. C. Fletcher, Royal Free Hospital.

*Chemistry*.—H. W. Phillips, Manchester.

*Materia Medica and Pharmacy*.—G. C. M. Davies, Charing Cross Hospital; A. B. Gosse, Royal Free Hospital; G. H. Henry, Belfast; and P. S. Hopkins, London Hospital.

### PART II.

*Anatomy*.—R. S. Dollard, Royal College of Surgeons in Ireland; G. H. Henry, Belfast; A. C. Jenkins, London Hospital; and J. D. Staley, Manchester.

*Physiology*.—H. Bennett, Manchester; R. S. Dollard, Royal College of Surgeons in Ireland; G. H. Henry, Belfast; P. J. Martin, St. Bartholomew's Hospital; J. O. Sergeant, Leeds; J. D. Staley, Manchester; D. A. Stepany, Royal Free Hospital; and R. J. S. Verity, Charing Cross Hospital.

**UNIVERSITY OF DURHAM**.—At the Convocation held on Sept. 28th the following degrees and diploma were conferred:—

*Doctor in Medicine*.—Henry Edward Davison, M.B., B.S., B.Hy. Durh.; Herbert George Harris, M.B., B.S. Durh.; Henry Douglas Johns, M.B., B.S. Durh.; Albert Ezra Neale, M.B., B.S. Durh.; Vaughan Pendred, M.B. Durh., F.R.C.S.; Arthur Riley, M.B., B.S. Durh. (*in absentia*); Frederick William Rowland, M.B., B.S. Durh.; Alfred Edward Stevens, M.B. Durh.; Ralph Harry Vincent, M.B., B.S. Durh., M.R.C.P., and Leslie Herbert Walsh, M.B., B.S. Durh.

*Doctor in Medicine for Practitioners of 15 years' standing*.—William Robert Etches, M.R.C.S., L.R.C.P., D.P.H.; Charles Joshua Joseph Harris, L.S.A., M.R.C.S., L.R.C.P.; John Henry Harris, M.R.C.S., L.S.A., D.P.H.; Edwin Guy Hunt, M.R.C.S., L.R.C.P.; James Thomas Neech, L.R.C.P., L.M., L.F.P.S.G., D.P.H., and William Henry Wright, M.R.C.S., L.K.Q.C.P. Irel., L.S.A.

*Master in Surgery*.—Bertram Crossfield Stevens, M.D., B.S., F.R.C.S. Eng., L.R.C.P., L.S.A.; and George Grey Turner, M.B., B.S. Durh., M.R.C.S., L.R.C.P.

*Bachelor in Medicine (M.B.)*.—Curtis Crispin Adeniyi-Jones, College of Medicine, Newcastle-upon-Tyne; Arthur John Spiller Brandon, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Clifford Harold Brookes, L.S.A., St. George's Hospital; Thomas Seymour Coates, College of Medicine, Newcastle-upon-Tyne; George Ernest Froggatt and Philip Gell Garrett, M.R.C.S., L.R.C.P., Middlesex Hospital; Charles Henry Gibson, College of Medicine, Newcastle-upon-Tyne; John Spencer Hall, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Robert Simpson Hindmarch and Albert Ernest Hodge, College of Medicine, Newcastle-upon-Tyne; Ernest George Klumpp, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Ernest Edward Norman and Alfred Parkin, College of Medicine, Newcastle-upon-Tyne; George Woodvatt Procter, M.R.C.S., L.R.C.P., Middlesex Hospital; Frederick Riddle Scott and John Ernest Sidgwick, College of Medicine, Newcastle-upon-Tyne; and Richard Thorne-Thorne, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital.

*Bachelor in Surgery (B.S.)*.—Curtis Crispin Adeniyi-Jones, College of Medicine, Newcastle-upon-Tyne; Arthur John Spiller Brandon, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Thomas Seymour Coates, College of Medicine, Newcastle-upon-Tyne; George Ernest Froggatt and Philip Gell Garrett, M.R.C.S., L.R.C.P., Middlesex Hospital; Charles Henry Gibson, College of Medicine, Newcastle-upon-Tyne; John Spencer Hall, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Robert Simpson Hindmarch, College of Medicine, Newcastle-upon-Tyne; Ernest George Klumpp, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Ernest Edward Norman, Alfred Parkin, Frederick Riddle Scott, and John Ernest Sidgwick, College of Medicine, Newcastle-upon-Tyne; Alfred Edward Stevens, M.B., St. Thomas's Hospital; and Richard Thorne-Thorne, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital.

*Bachelor in Hygiene (B.Hy.)*.—Thomas Morrison Clayton, M.B., B.S. Durh.; and Thomas Yeates, M.B., C.M. Ed.

*Diploma in Public Health (D.P.H.)*.—Thomas Morrison Clayton, M.B., B.S., B.Hy. Durh.; Henry Edward Davison, M.B., B.S., B.Hy. Durh.; Duncan Macfadyen Millar, M.B., C.M. Glasg., B.Hy. Durh.; Edgar Mitchell, M.D., B.S., B.Hy. Durh.; and Thomas Yeates, M.B., C.M. Edin., B.Hy. Durh.

**UNIVERSITY OF GLASGOW**.—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated (B., Botany; Z., Zoology; P., Physics; and C., Chemistry):—

John Andrew Aitken (B., Z.), George Allison Allan (B., Z., P., C.), Robert Anderson (Z.), James Henderson Baird, B.A. (B., P.), Edgar Barnes (B., P.), George Duncan Morrison Beaton (B.), John Charles Bosworth (C.), Donald Livingstone Carmichael (B., P.), John Paterson Carmichael (B., C.), Charles Game Angus Chislett (Z., P.), Donald Clark (B., P.), James Alexander Cowie, B.A., B.Sc. (B.), Arthur Muir Crawford (B., P.), Harold Windley Dempster (B., Z., P., C.), Robert Scott Dewar, M.A. (B.), Walter Duffy, M.A. (Z., P.), John Shaw Dunn (Z.), Eric John Dyke (B., C.), Hamilton William Dyke (B., P.), James Fairley (B., P.), Harry Prescott Fairlie (B., P.), Alexander Burns Ferguson (B., P.), Thomas Henderson Forrest (B., P.), James Wilfred Georgeson (B.), William Gilbert (B., P.), Joseph Glaister (C.), Alexander Graham (Z.), John Isdale Greig (B., Z.), William Grier (B., P.), Robert Neil Guthrie (B., P.), Charles Francis Dyer Hammond (P., C.), John Hammond

(B., Z.), Frank Hauxwell (B., P.), Robert McCowan Hill (C.), Lawrence Hislop (C.), Ralph Howell (C.), Alexander Hunter (P.), David Guthrie Hunter, M.A. (Z.), William Boyd Jack (B., P.), Arnold Ernest Jones (Z., P., C.), Percy James Kelly (B., Z.), John Keys (B., P.), James Dunlop Kidd (B., P.), James Towers Kirkland (P.), William Love Kirkwood (B., P.), Peter Lowe, M.A., B.Sc. (B., Z.), Angus Macaulay (Z., C.), John Duncan MacCallum, M.A. (B., Z.), John MacCartney (B., Z.), Thomas McCosh (B., Z.), David MacDonald (B., P.), Duncan McEwan (B., P.), John MacIntyre (B., P.), Finlay John Mackay (P., C.), Hugh MacNaught (B., P.), Richard Cameron Macpherson (Z., P.), Peter Maguire (B., Z., P., C.), John Miller (B., P.), William Miller (B., P.), Henry Joseph Milligan (B., P.), Robert Wright Mitchell (B., P.), John Moffatt (Z.), Kenneth Morrison (P., C.), Arthur Geoghegan Paxton (B., P.), Thomas Thomson Rankin (B., P.), Daniel McKinlay Reid (B.), James Mill Renton (B., P.), Arthur Robertson (B., P.), James Henry Anderson Robertson (B.), William Rolland (Z., P.), Alexander Cappie Russell (B., P.), John Cooper Russell, M.A. (B., C.), James Charles Donaldson Simpson (P., C.), Robert Alexander Slater (Z.), Thomas Baillie Smith (B., P.), Arthur Anderson Stewart (P., C.), Daniel Stewart (B., P., C.), John Logan Stewart, M.A. (B., Z., P., C.), Thomas Strain (B., Z., C.), William Alexander Stuart (B., P.), Joseph Roderick Sutherland (B., P.), William Robb Taylor (B., C.), Thomas Thom (B., P.), Charles Sanson Thomson (B., P.), Robert Todd (B., P.), William Young Turner, M.A. (B., Z.), James Kennedy Welsh (Z.), and George Young (B., P.). Women.—Bethia Shanks Alexander (P.), Jeannie Thomson Clark (B., Z.), Annie Rennie Hird (B., Z.), Rose Isobel Hudson (B., Z.), Katharine Robina Margaret Lucas (P.), Agnes M'Phun (C.), Elizabeth Maud M'Vail (B., Z.), Margaret Walker Millar (P., C.), Edith Oversby (B.), Vera Dagmar Reis (B., Z.), Lily Smellie (P.), and Margaret Baillie Taylor (B., Z., P.).

The following have passed the second professional examination in the subjects indicated (A., Anatomy; P., Physiology; and M., Materia Medica and Therapeutics):—

Robert Adam (M.), Adolph Anderson (P.), James Richard Sumner Anderson (P., M.), Thomas Bennett, M.A. (M.), Archibald Grainger Biset (A., P.), Alexander Blair (A.), Robert George Bradford (P., M.), John Brown (P.), Carl Hamilton Browning (A., P., M.), John Miller Hopkins Caldwell (A.), Andrew Connal (A., P., M.), John Cross (A.), Hugh Collin Davies (A., M.), David Dickie (M.), James Forsyth (A., P., M.), William Macmillan Gilmour (P., M.), James Glover (A., P.), George Gordon (P.), John Hanson, M.A. (A., P., M.), Saul Hyman Harris (M.), William Harvey (M.), John Monnetto Huoy (A., P.), Malcolm Hutton, M.A. (A., P., M.), Alexander Jamieson (P., M.), John Muir Kelly (A.), Alexander Dingwall Kennedy (A., M.), Robert Dallas Kennedy (P.), Alexander Leggat (P.), Archibald Leitch (A.), William Jamieson Logie (P.), Thomas Walker Love (M.), Donald Macaulay (A., P.), John Bertram McCabe (P., M.), John Finlay Macdonald (A., P.), David Duncan Fraser Macintyre (P.), Norman Alexander Macleod (A., P., M.), Andrew Alexander M'Whan (P.), Alexander Matheson, M.A., B.Sc. (M.), John Baird Morton (A., P., M.), Gavin Muir (A.), James Carmichael Palmer, M.A. (A., P., M.), Daniel Stevenson Richmond (P., M.), George Richmond (A., P., M.), Peter Hamilton Robertson (M.), Robert Thin Craig Robertson (M.), Campbell Ross (A., P.), Lawrence Drew Shaw (P.), John Macgregor Smith (P., M.), John Black Stevenson (M.), Wm. David Henderson Stevenson, M.A. (M.), John Stewart (A., M.), Norman Burgess Stewart (A., P.), William Stewart (M.), Peter Lindsay Sutherland (M.), Joseph Walker, M.A. (M.), Alexander Macmillan Watson (M.), Robert Watson (P.), William Norman West Watson (M.), Griffith John Williams (M.), Archibald Simpson Wilson (A.), Robert M'Nair Wilson (A., P.), Eldred Wright (A.), Hugh Young (M.), and John Young, Glasgow (M.). Women.—Jeanie Auld (M.), Agnes Wallace Cameron (M.), Mary Charlotte Cameron (M.), Jane Campbell (A.), Jessie Galloway Duncan (M.), Kate Fraser, B.Sc. (M.), Jane Reid Foulds Gilmour (M.), Margaret Hardy (M.), Mary Lauchline McNeill (M.), Anna Pollock Martin (A.), Eliza Jane Miller (M.), Isabel Deane Mitchell (M.), Margaret Hassock Smart (M.), Jessie Marie Stewart (M.), and Janet Gardner Waddell (M.).

The following have passed the Third Professional Examination in the subjects indicated (P., Pathology; and M., Medical Jurisprudence and Public Health):—

William Armitage (P.), Robert James Arthur (P., M.), Robert Bryson (P.), Angus Campbell (P., M.), Robert Harold Campbell (P., M.), Alexander Adam Carruthers (M.), Robert Peopce Cartwright (M.), John Cairns Christie, M.A. (P., M.), Samuel Campbell Cowan (P., M.), James Craig (P., M.), James Dick, M.A. (P., M.), Mitchell Innes Dick (M.), Donald Douglas, M.A. (M.), William Dow (M.), William White George (P., M.), John Andrew Hagerty (M.), John Kennedy (P.), Daniel Douglas M'Dougall, M.A. (M.), Alexander Armstrong MacFarlane (P., M.), John Matheson Mackellar (M.), Ivy M'Kenzie, M.A., B.Sc. (P., M.), James Roy M'Vail (P., M.), Robert Harry Manson (P.), Robert Menzies (M.), Alexander John Mitchell (P., M.), John Mark Reid (M.), Norman Cumming Rogers (M.), James Russell (P.), Frank Donald Scott (M.), John Barbour Stewart (P., M.), John Restell Thomas (M.), John Forrest Weston (M.), Joseph White, M.A., B.Sc. (P., M.), and John Wilson (P.). Women.—Helen Stephen Baird, B.A. (M.), Gertrude Dorman Bostock, B.Sc. (P., M.), Margaret Edith Bryson (P., M.), Ethel MacLeod Lochhead (P., M.), and Edith Christine Wallace (P., M.).  
\* With distinction.

**POISONOUS FUNGI**.—An inquest was held at Plymouth on Sept. 30th upon a man, aged 42 years, who was taken ill after eating some "mushrooms" purchased from a hawk on Sept. 21st. He died on Sept. 29th. His wife, who had also partaken of the same food, felt no ill-effects. Medical evidence showed that death was due to poisoning by eating fungi which resembled mushrooms, and a verdict of "Death through misadventure" was returned.

**HOSPITAL SATURDAY FUND.**—The quarterly meeting of the board of delegates of the Metropolitan Hospital Saturday Fund was held on Oct. 5th at the offices of the Fund, 54, Gray's Inn-road, W.C. The report of the finance committee showed that the receipts from the workshops, &c., from Jan. 8th to Sept. 14th had amounted to £9865 12s. 8d., as compared with £9128 6s. 5d. at the corresponding period of last year. The expenditure since January had reached £1343 5s. 10d. The sum of £6000 had been placed on deposit at the bankers, and £3134 16s. 1d. had been advanced to the premises fund. For the twenty-ninth consecutive year Hospital Saturday will be observed in London and the suburbs on Saturday, Oct. 12th. The regular weekly collection in the industrial establishments, which will be continued until the end of December, at the present time amounts to nearly £1000 in advance of the sum contributed at a corresponding period of last year.

**A CHARGE OF FRAUD.**—The *Times* of Oct. 8th reports that at Marylebone W. Dyer Frazer, 44 years of age, *alias* Robert Wilson and Sergeant Bertram, described as a surgeon, was charged, on remand, with attempting to obtain charitable contributions from Dr. Theodore D. Acland of Bryanston-square and others by false pretences. It appeared that on July 9th Dr. Acland received a begging letter purporting to come from Mr. W. Dyer Frazer, one of his old pupils at St. Thomas's Hospital, who is now in Johannesburg. The letter was dated from a street at Brighton. Dr. Acland communicated with the secretary of the Medical School at St. Thomas's Hospital and then wrote to Mr. H. C. Crouch of Welbeck-street, Mr. Frazer's brother-in-law. Mr. Crouch immediately recognised the letter as being similar to others received from several other medical men, including Sir William MacCormac, which had been sent on to him, and, knowing that they were not in his brother-in-law's handwriting he communicated with the police. A further charge was now preferred against the prisoner of forging the endorsement of a cheque for £10 and uttering the same, thereby defrauding Mr. J. F. Churchill, of Chesham. Mr. Travers Humphreys, barrister, prosecuted for the Medical Defence Union. Mr. Churchill stated that at one time he was a student at Charing-cross Hospital. On March 21st he received the following letter purporting to be signed by Walter H. Haw, M.R.C.S., L.S.A.:—"Private. Dear Sir,—Under the following very special and exceptional circumstances I beg to solicit, as an old Charing-cross man and ex-H.P., your most kindly offices. I have been in practice in Barberton in the Transvaal, South Africa, and on the outbreak of the war had to decide between losing my all or taking up arms for the Boers. I chose the former alternative, with the result that I have returned here, Air-street, Brighton, penniless and in the greatest straits. To enhance my trials I have a wife and child to support. I am now trying to obtain some help from a benevolent institution, B.M.A. Will you as an act of truest kindness support my appeal? And can you extend me help in any other way? Awaiting your kind reply, I am, Sir, yours truly," and signed as above. The witness wrote asking for references and was referred to two medical men, living at Northampton and Welwyn, who were described as colleagues of the writer at Charing-cross. The witness wrote to these gentlemen and, believing the writer of the letter was the person he represented himself to be, he sent a cheque for £10, which was duly paid by the bank and endorsed "Walter H. Haw." Subsequently, he received other letters from the same person, and at length he wrote to Mr. W. H. Haw at Barberton, and in consequence of his reply he communicated with the Medical Defence Union. Mr. Humphreys said that one of the subsequent letters had a deep black edge and asked for a further £10 as the writer's "dear wife" was dead. Other witnesses were called to show that the prisoner arranged with a newsagent at Air-street, Brighton, to receive letters in the name of Haw. A great many letters were received in that name, and these were given to a woman who took them to the prisoner. This woman had known the prisoner for two years. He had been in England during that time and had neither wife nor children. The prisoner was arrested by Detective-sergeant Harris in the hop-fields at Yalding in Kent. He admitted that he sent the letter, the subject of the first charge, and in regard to the other said that the letters and the endorsement on the cheque were in his handwriting. The detective

informed the court that there were eight other similar cases, but the persons concerned would not prosecute. Mr. Plowden committed the prisoner for trial.

**BRITISH MEDICAL TEMPERANCE ASSOCIATION.**—Dr. T. B. Adam has just been appointed assistant secretary of the British Medical Temperance Association, which now numbers more than 1000 members and student associates. Dr. Adam's address will be that of the honorary secretary, Dr. J. J. Ridge, Carlton House, Enfield, and he will specially devote himself to work among medical students.

**MR. J. LYNN THOMAS, C.B., F.R.C.S. Eng., L.R.C.P. Lond.**—At the meeting of the committee of the Cardiff Infirmary held on Oct. 2nd, a resolution was passed expressing the heartiest congratulations of the committee to Mr. J. Lynn Thomas on his being appointed a Companion of the Order of the Bath, a distinction awarded to him in recognition of his services in South Africa.

**VACCINATION QUESTIONS.**—At a meeting of the Helston Board of Guardians held on Sept. 28th a letter was read from the Local Government Board drawing attention to the unsatisfactory state of vaccination in one of the parishes of the union, and requesting the guardians to inform the public vaccinator that if he did not perform his duties another must be appointed to do so. The guardians eventually decided to write to the public vaccinator complaining of, the assistant clerk remarking that unless the board of guardians did their duty by dealing with defaulters they could hardly expect the public vaccinators and vaccination officers to do theirs.

**FATAL ACCIDENT TO A MEDICAL MAN.**—An inquest was held at Chippenham on Oct. 4th concerning the death of Dr. David Reid Crow, whose body was found lying on the Great Western Railway line near Chippenham. Evidence showed that Dr. Crow had taken a ticket from Plymouth to Paddington on Oct. 2nd and at Chippenham the door of the railway-carriage in which he journeyed was found open. Medical evidence showed that the neck was fractured and a verdict of "Accidental death" was returned. Dr. Crow, who was a native of Ardrishaig, Argyllshire, was 32 years of age and was unmarried. He studied medicine at Edinburgh University, graduating M.B. and C.M. in 1893. For a few years afterwards he practised in Barnes, near London, until last year he accepted a Government appointment in West Africa. Whilst at Kumasi he contracted malarial fever and had only just returned on leave to England.

**EPSOM COLLEGE.**—At a meeting of the Council of Epsom College held on Oct. 2nd, when the Rev. E. W. Northey occupied the chair, a silver tea and coffee service was presented to the Rev. Dr. Rowton, as a personal testimonial from the members of the Council, all of whom had contributed towards its purchase. The following inscription appeared on the tea and coffee pots:—"Presented to the Rev. S. J. Rowton, M.A., Mus. D., by the members of the Council of Epsom College, in recognition of his devotion to the best interests of the School during thirty years. July, 1901." In presenting the testimonial the chairman referred in cordial terms to the long period during which Dr. Rowton had been connected with the College and to his valuable and varied services to the school. He observed that the pleasure of the Council in making the presentation was linked with regret at the loss of so valued a teacher. On behalf of his colleagues and of himself he expressed the hope that health and happiness would attend Dr. Rowton and his family in their new home. Dr. Rowton replied in happy terms, expressing his most hearty thanks to the Council for their recognition of his work.

**ENTRANCE SCHOLARSHIPS.**—At King's College Hospital the following Entrance Scholarships have been awarded:—Medical Entrance Scholarships: P. A. Mansfield, 70 guineas; W. Hart, 60 guineas. Sambrooke Medical Exhibition (Science): F. C. H. Powell, £60. Clothworkers' Company Exhibitions (Science): N. G. Langrish, £30 for two years; G. W. N. Rose, £20 for two years. Warneford Medical Scholarships (Arts): H. L. Gauntlett, £25 for three years; C. A. Narlian, £25 for three years. Epsom Scholarship: J. L. Burford, £135.—The following awards have been made in the Faculty of Medicine at University College, London:—Medical Entrance Scholarships—Bucknill Scholarship, £30 a year for four years, J. A. Watt; 60 guineas

Scholarship, H. R. Evans; 60 guineas Scholarship, L. F. Hirst. Medical Exhibitions, each 80 guineas, J. A. Ferrière and E. E. Maples.—At the Westminster Hospital Medical School the entrance scholarships competed for before the beginning of the winter session have been awarded as follows:—Epsom Scholarship, of the value of 110 guineas, J. M. Platt; Scholarship in Arts, of the value of £60, R. S. Statham, Dover College; Natural Science Scholarship, of the value of £60, A. C. Bryson; University Scholarship, of the value of £40, J. H. Hebb, St. John's College, Oxford; Scholarship in Arts, of the value of £40, H. Galloway, St. Paul's School; and a Scholarship in Arts, of the value of £30, C. C. Hickey.

**WATER-SUPPLY OF PADSTOW.**—The Local Government Board inspector recently held an inquiry at Padstow, Cornwall, into the application of the urban district council for leave to borrow £4535 for the purpose of a water-supply for this seaside resort.

**DEATHS OF CENTENARIANS.**—Mrs. Spurway died at Barnstaple last week at the age of 101 years and five months.—The death is announced of Madame Thiollier, aged 103 years, at Lombreuil. She has left 92 children and grandchildren.

**CHARITABLE REQUESTS.**—By the will of the late Mr. Robert Currie Murray, of Kirkconnel Lea, Sydenham-road, Bristol, the Royal Infirmary at Dumfries receives £500, Mr. Barnardo's Homes £300, and the Royal Infirmary at Bristol, the Bristol General Hospital, the Bristol Dispensary, and the Children's Hospital at Bristol £100 each.

**A NEW HOSPITAL FOR WHITBY.**—On Sept. 28th Lady Cecilia Turton opened the new permanent Cottage Hospital erected in Grape-lane, Whitby, which occupies the site of the old premises of the York Union Bank. The new building has cost about £1100, towards which sum £300 are still required. The hospital has been fitted with the latest modern improvements. It may be of interest to note that Captain Cook, the circumnavigator, lived next door to the present building.

**BRISTOL GENERAL HOSPITAL.**—A special general meeting of the governors of this institution was held on Oct. 7th, when Dr. George Parker was appointed physician to the hospital, vice Dr. Alfred James Harrison, resigned. Dr. Harrison was appointed physician in charge of the skin department of the hospital. There were three candidates for the post of assistant physician vacant by the resignation of Dr. Parker, and Dr. Newman Neild was eventually elected.

**FREEMASONRY.**—*The Rahere Lodge, No. 2546.*—A meeting of this lodge was held on Oct. 8th at Frascati's Restaurant, Oxford-street, London. W. Bro. Phineas S. Abraham, M.D., W.M., being in the chair. Bro. Whitaker was admitted to the third degree and Bros. Keown and Scott to the second degree. Mr. Arthur J. Edge, M.B. Lond., was initiated into Freemasonry and Bro. T. B. Carlyon, M.R.C.S. Eng., St. George's Lodge, No. 125, was unanimously elected a member of the lodge. The brethren and a number of guests afterwards dined together.

**ADDED MILK IN BUTTER.**—In THE LANCET of Sept. 21st, p. 779, it was mentioned that Messrs. Pearks, Gunston, and Tee, grocers, had been condemned in three different places to pay fines and costs amounting to £60 for selling butter containing more than 16 per cent. of moisture. The same defendants having been recently summoned before the Taunton borough justices for a like offence—namely, the sale of butter re-churned with milk—the bench dismissed the summons, on the ground that the label was sufficiently descriptive and that there had been no sale to the prejudice of the purchaser.

**THE NATIONAL REGISTRATION OF PLUMBERS.**—The Mayor of Tunbridge Wells (Alderman W. H. Delves) presented certificates of registration to master and operative plumbers at a meeting at the Town Hall, Tunbridge Wells, on Oct. 3rd. He was supported by Alderman Lutwidge, Alderman Cronk, and other members of the corporation, who expressed their sense of the need for the national registration of plumbers in the public interest.—Mr. W. H. Bishop, who represented the Plumbers' Company, sketched

the origin of the movement, the resolve of the craft to insure respect for plumbing work, the demands for registration that came from all sides, the formation and constitution of registration committees, the gradual growth in them of tests in practical work, the importance of practical tests, and the appreciation of the craft shown by adhesions equal to over one-third of the plumbers of the United Kingdom to a voluntary association exercising authority to which they declared allegiance. He described the importance attached by plumbers to an Act of Parliament which would put difficulties in the way of those who were not registered but pretended that they were, and glanced at the opposition made by interested parties. He praised the intelligence of those who from the desire to see plumbing work well done had supported the registration movement, suggesting that if one in 10 might be taken to represent the really intelligent men in any great trade plumbers (registering over one-third of the whole) might claim that their intelligent members of the craft were as one in three, a much larger proportion.—Mr. A. Markins, an operative plumber, expressed the hope that in the new technical institute provision would be made for practical as well as theoretical classes.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

- BARR, J., M.B., M.S. Glasg., has been re-appointed Medical Officer of Health of the Urban District of Rishton.
- BONNEY, W. F. VICTOR, M.D., M.S. Lond., F.R.C.S. Eng., has been appointed Physician to Out-patients, Chelsea Hospital for Women.
- BYFORD, W. F., M.R.C.S. Eng., L.R.C.P. Lond., has been re-appointed Medical Officer of Health of the Borough of Ruthin.
- COLLARD, F. S., F.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory Acts for the Croydon District of Surrey.
- COLLINS, EDWARD TENISON, M.R.C.S., L.S.A., has been appointed Honorary Gynaecologist to the Cardiff Infirmary.
- COUTTS, F. J. H., M.D. Vict., D.P.H., has been appointed Medical Officer of Health of the Borough of Blackpool.
- DOBBS, K. D. B., L.R.C.P., L.R.C.S. Irel., has been re-appointed Medical Officer of Health of Tutbury.
- GRIFFITHS, A. F., M.D. Harvard, has been appointed Clinical Assistant, Chelsea Hospital for Women.
- HAY, JOHN, M.D. Vict., M.R.C.S. Eng., L.R.C.P. Lond., has been re-appointed Medical Tutor and Registrar to the Royal Infirmary, Liverpool.
- HILL, ERNEST, L.R.C.P. Lond., M.R.C.S., D.P.H., has been appointed Health Officer for the Colony of Natal.
- KELLY, BRUCE, M.B., C.M. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Deputy Medical Officer by the Wells (Somerset) Board of Guardians.
- LAMB, J. M. A., L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator for the Second District, Poole Union.
- LEHMANN, J. E., M.B. Toronto, L.R.C.P., M.R.C.S., has been appointed Assistant Surgeon to the German Hospital, London.
- MARSHALL, LEIGH-RICHMOND, L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator to the Mary Tavy District of the Tavistock Union.
- MATTHEWS, J. F., M.R.C.S. Eng., has been appointed Public Vaccinator for the South-Western District, Victoria.
- MCCALL, EVA, M.B., B.S. Glasg., has been appointed Resident Medical Officer at the Birkenhead Union Infirmary.
- MCCARDEL, E. J., M.D., Ch.M., M.R.C.S. Eng., has been appointed Clinical Assistant, Chelsea Hospital for Women.
- MONTGOMERY, SAMUEL, L.R.C.P., L.R.C.S. Edin., has been appointed District Medical Officer and Public Vaccinator to the Branksome District, Poole Union.
- MURRAY, A. H., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer at Cunnamulla, Queensland.
- PRINGLE, ARTHUR Y., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Honorary Medical and Surgical Officer to the East Suffolk and Ipswich Hospital.
- SHERREN, JAMES, F.R.C.S. Eng., has been appointed Surgical Registrar to the London Hospital.
- TURNER, A. H., L.S.A., has been appointed Medical Officer and Public Vaccinator of the Beaconsfield District of the Amersham Union.
- VON MURALT, WILLY, M.D. Zürich, has been appointed Clinical Assistant, Chelsea Hospital for Women.
- WADDINGTON, W. HEYWOOD, M.B. Vict., L.S.A., has been appointed Medical Officer of Health for Scarborough.
- WHITEHOUSE, W. H., M.D. Durh., has been appointed Honorary Medical Officer to the Birmingham Lying-in Charity, vice Mr. Clement Hadley.
- WILLIAMS, LEONARD, M.D. Glasg., has been appointed Assistant Physician to the German Hospital, London.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

- BIRMINGHAM GENERAL DISPENSARY.**—Resident Surgeon, unmarried. Salary £150 per annum, with rooms, fire, lights, and attendance.
- BRADFORD ROYAL INFIRMARY.**—House Surgeon, unmarried. Salary £110 per annum, with board and residence. Also Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.
- BRISTOL GENERAL HOSPITAL.**—Assistant House Surgeon. Salary £70 per annum, with board, residence, &c.
- CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY,** Sloane-square, Chelsea, S.W.—Honorary Surgeon.
- CHELSEA HOSPITAL FOR WOMEN,** Fulham-road, S.W.—Registrar. Honorarium 20 guineas per annum.
- CITY ASYLUM,** Birmingham.—Junior Assistant Medical Officer, unmarried. Salary £150 a year, with board, apartments, and washing.
- CORNWALL COUNTY ASYLUM,** Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, apartments, laundry, &c.
- COUNTY ASYLUM,** Mickliver, Derby.—Junior Assistant Medical Officer. Salary £110, rising to £130 per annum, with apartments, board, washing, and attendance.
- DENBIGHSHIRE INFIRMARY,** Denbigh.—House Surgeon. Salary £100, with board, residence, and washing.
- DESEX COUNTY ASYLUM,** Brentwood.—Junior Assistant Medical Officer. Salary £140 per annum.
- GREAT NORTHERN CENTRAL HOSPITAL,** Holloway, N.—Surgeon.
- GUY'S HOSPITAL MEDICAL SCHOOL.**—Gordon Lectureship in Experimental Pathology. Salary, with fees, £250 per annum.
- HOSPITAL FOR SICK CHILDREN,** Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, washing allowance £2 10s., with board and residence; also Surgeon Dentist.
- HOSPITAL FOR WOMEN,** Liverpool.—House Surgeon for six months. Honorarium £25.
- HUDDERSFIELD INFIRMARY.**—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.
- HOSPITAL FOR WOMEN,** Soho-square, W.—Assistant Physician.
- INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.**—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.
- MANCHESTER MONSALL FEVER HOSPITAL.**—First Medical Officer. Salary £150 per annum, with board and lodging.

- YORK DISPENSARY.**—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory Acts at Foyers, Invernesshire; at Shilton, Warwickshire; at Wells, Norfolk; and at Sherston, Wiltshire.

## Births, Marriages, and Deaths.

### BIRTHS.

- FOULDS.**—On Oct. 8th, at Ashlea, Droitwich, the wife of Francis H. Foulds, M.R.C.S., L.R.C.P. Lond., of a daughter.
- TINLEY.**—At Hildegarde House, Whitby, Sept. 8th, the wife of W. E. F. Tinley, M.D., twin daughters.

### DEATHS.

- SMITH.**—On Oct. 1st, at Machadodorp, Transvaal, of dysentery, Hugh Beaumont Smith, M.B., B.Ch., B.A.O. Irel., Civil Surgeon, aged 25.
- THOMSON.**—On Oct. 6th, at Beochhurst, Camberley, Surrey, Surgeon-Major-General William Arthur Thomson, Honorary Physician to the King, aged 71.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments, and Answers to Correspondents.

### ALLEGED WANT OF SKILL NO ANSWER TO A CLAIM FOR ATTENDANCE.

At the Southwark County Court on Tuesday, Oct. 1st, before his Honour Judge Addison, K.C., Dr. James Wills, of 232, Old Kent-road, sued Joseph Payne, to recover £10 9s. for professional attendance on, and medicine supplied to, Mrs. Payne.—Mr. Philcox, solicitor, appeared for the plaintiff.—Dr. Wills said that he attended Mrs. Payne during seven months, paying her 32 visits, making two special examinations, one operation which occupied two hours and in connexion with which he paid another medical gentleman £1 1s. for administering chloroform, and supplying 32 bottles of medicine, 11 bottles of lotion, powders, &c. He sent in his bill for £10 9s., which was a reasonable charge, and no complaint was made until the present summons was issued.—The Defendant declared that all that this bill covered was done by the medical practitioner to rectify an error he made when his wife was first confined.—The Plaintiff: That was two years ago, and she has been confined by another doctor since. She came back to me after that.—The Defendant: The doctor who attended at the second confinement found out the injury done at the first.—His Honour: As there is no counter claim against the doctor for want of skill that is no answer to this action. It is rather hard on the doctor to suggest want of skill after all this long time and after another confinement by another medical man. But why did you come back to Dr. Wills after he had, as you suggest, done wrong?—The Defendant: Because of what the doctor told me at the second confinement. She has had to undergo an operation and cannot come to-day.—His Honour: The suggestion of want of skill is no answer to this bill. That would be matter for a cross action or a counter claim, but it would be a very difficult thing to prove. I am not in the least inclined to suggest such an action, because I know of no class of case which is more expensive or troublesome or difficult of proof than negligence against a medical man after such a lapse of time.—Dr. Wills: I was accompanied by another medical man, and we gave her chloroform as it was a very difficult case, but she got perfectly well.—The Defendant: The doctor used instruments against my wish.—His Honour: That is no answer to this bill.—The Defendant: Will you adjourn the case until my wife is able to attend?—His Honour: I should do you no earthly good by adjourning this; it would only pile up costs against you and waste the time of the doctor. I cannot allow that. If you have a grievance against the doctor you must bring an action against him. At present he is entitled to this amount, and therefore I give judgment for him for the amount claimed and costs.—Judgment was entered accordingly.

### A POINT IN VACCINATION LAW.

To the Editors of THE LANCET.

SIRS,—I shall be much obliged if you will kindly answer in the next number of THE LANCET what I am going to ask you. I am a public vaccinator and sent a notice to the father of a child saying I would call and offer to vaccinate, &c. By return of post I received a letter from the father containing his address, signed with his full name, and saying "it will be no use you visiting the home of — [giving his child's name] for I will not have her vaccinated," the words in italics just as I have written them. The man is a farmer, in a good position, and not being my patient I did not call at the house. I want to know if, in the face of the father's decided refusal of vaccination, it is necessary for me to visit the house in order to render successful any proceedings taken against the father of the child by the vaccination officer. I am, Sirs, yours faithfully,

Oct. 3rd, 1901.

\*.\* Yes, it is necessary.—ED. L.

BOOTE.

### A LEGAL QUERY.

JUDICIAL ignorance is proverbial, but legal ignorance is, if we may judge by the following story, not confined to the bench. A lady applied through her solicitors to an insurance office for insurance on her life. The office replied to the solicitors that they could not entertain the proposal to insure Mrs. — "on account of her menopause not being yet established." The solicitors thereupon wrote back to the office:—

"Gentlemen,—What is a menopause? and what steps, if any, would you recommend us to advise Mrs. — with a view to getting her menopause established or filed?"

\*.\* This letter was type-written, with the exception of the last two words, which were in ink.—ED. L.

### THE WATER-FAMINE IN THE NORTH.

THE *Batley Reporter* of Oct. 4th attributes to the medical officer of health of Batley the following statement: "The dark colour of the water at Batley just now will do nobody any harm. He had tested the water and found it perfectly free from any signs of decomposition. 'Boiling and filtering might suit sentimentalists, but it spoiled the water and there was no need for it.'

We do not know the state of the water at Batley, and possibly the medical officer of health is correct in saying that the public might drink it with impunity, but to make such a general statement as he is reputed to have done is certainly to expose himself to criticism. Under certain circumstances not to boil the water would be to court a great danger in drinking it, and if the water at Batley is dark-coloured the term "sentimentalists" can certainly not be applied to those who would take the very wise precaution of filtering and perhaps of boiling it also before drinking it. Certain fevers have been proved to be waterborne, but boiling destroys the germs and renders the water fit for drinking purposes as far as disease germs are concerned.

#### DOMEN STRAIGHT-FRONTED BELT CORSET.

THE Domen Belt Co., of 406, Strand, London, W.C., have submitted to us their straight-fronted belt corset, which they have designed with a view to the avoidance of compression in the epigastric and umbilical region and which they state will especially meet the requirements of those suffering from certain abdominal troubles. The combination of corset and belt is well designed and is a great advance on the separate articles usually employed. The elasticity of the straight-fronted belt corset goes a long way towards reducing the possibility of too tight-lacing and it is pronounced to be very comfortable.

#### "HIGH FREQUENCY CURRENTS AND DIABETES."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "S. L. B. W." re High Frequency Currents and Diabetes in THE LANCET of Oct. 5th we have record of an exceedingly interesting case treated by high frequency currents as employed here. The patient was a chief engineer in the American Navy at Santiago. The sugar in his urine was reduced very greatly, almost to vanishing point, his weight increased, and his general health was completely restored. We shall be pleased to send you detailed particulars if favoured with an application from your correspondent.

I am, Sirs, yours faithfully,

JOHN D. MARSHALL.

he Electrical Ozone and Light Treatment, Hanover-square, W.,  
Oct. 7th, 1901.

To the Editors of THE LANCET.

SIRS,—The following references may assist "S. L. B. W." :—Bordier (Précis d'Electrothérapie, p. 532), abstract : "Results not conclusive. Messrs. Apostoli and Berlioz have in three cases seen the sugar disappear almost completely; treatment by auto-conduction. When the sugar has not diminished there has been a marked improvement in the general state. Owing to the different causes uniform results cannot be expected. However, the treatment ought to be tried in all cases if only for the improvement in the general state." Gaimbail (La Thérapie par les Agents Physiques, p. 517) has submitted several cases to auto-conduction without any result. There is, so far as I can see, no mention of the treatment of diabetes by high frequency currents in the Comptes Rendus des Séances du Ier Congrès International d'Electrologie et de Radiologie Médicales, Paris, 1900.

I am, Sirs, yours faithfully,

J. DODD.

Oct. 8th, 1901.

To the Editors of THE LANCET.

SIRS,—In answer to "S. L. B. W." re the value of high frequency electrical currents in the treatment of diabetes mellitus I beg to state that I have treated five cases. Four, very slight and early cases, lost all sugar and symptoms in a few weeks' treatment. The fifth case is a very old one and the weight improves and sugar goes quickly under treatment only to return after an interval of a few months. The patient is now under treatment for the third time and is gradually improving. I hope to be able to report these cases later. High frequency and high potential electrical currents are of the greatest use in all conditions of "wasting."

I am, Sirs, your faithfully,

C. W.

Oct. 7th, 1901.

#### "A DIFFICULTY UNDER THE NOTIFICATION ACT."

To the Editors of THE LANCET.

SIRS,—Under the above heading of proceedings against me by the Lunesdale Rural District Council, reported in your issue of Oct. 5th, is a mistake which might easily occur by a confusion of names. It is made to appear that I conducted the cross-examination of my opponent's medical witness, at the end of which it says, "Dr. Wingate-Saul submitted there was no case to answer," &c., &c., and, further, "Dr. Wingate-Saul's application for costs was refused," &c., &c.—whereas I never spoke in court, my case having been conducted by my son, Mr. E. W. Wingate-Saul, barrister-at-law, instructed by a firm of Lancaster solicitors. If you will kindly make this correction in your next issue I shall be obliged.

I am, Sirs, yours faithfully,

Oct. 6th, 1901.

W. W. WINGATE-SAUL.

#### A QUESTION OF ORTHOGRAPHY.

To the Editors of THE LANCET.

SIRS,—On reading the "Suggestions for the Care and Use of Paraffin Lamps" issued by the Education Department I noticed, as probably others have done, that the eighth paragraph is as follows: "Never refill (sic) the lamp when it is alight." Turning to page 928 of THE LANCET of Oct. 5th, where you reprint the somewhat lengthy document which is to puzzle or instruct the young mind and lead to the

puzzling or instruction of the parent corrected by the offspring, I found, without surprise, that in the injunction referred to you print "refill" as "re-fill." I confess myself to be on the side of your proof-reader or whoever corrected (as I believe) the spelling of the Education Department, and I may point out that you have on your side practically all the dictionaries, even the "Century Dictionary" which hails from across the Atlantic and would justify the Education Department if it sought to make its pupils spell "theatre" "theater," giving "refill" without an alternative spelling with one l. Johnson, however, and the "New Oxford Dictionary" alike give "fulfil" in preference to "fulfill" without excluding the latter, and I take it that the gentleman who drafted the lamp circular followed the analogy of "fulfil" either intentionally or unconsciously. I should rather like to know, however, what spelling will be adopted by schoolmasters and school inspectors who may strive to impress the circular on scholars by giving it to them as dictation, and what view would be taken by Civil Service examiners in those examinations for posts in Government offices and the services in which mistakes of spelling are jealously scrutinised and counted. "Refill," at any rate, cannot have been a misprint; it catches the eye too readily for successive readers to miss it—and I suppose that someone reads the circulars issued by Government departments after they leave the printers.

I am, Sirs, yours faithfully,

M.A. CANTAR.

Oct. 9th, 1901.

#### HOW DISEASE IS SPREAD.

A CASE of scarlet fever was recently reported to the medical officer of health of Leeds, who found that the patient, as soon as he knew the nature of the disease, had travelled to Southampton. The Leeds authorities communicated with the sanitary department of that port and the man has been summoned before a court of summary jurisdiction and fined 40s. and costs for appearing in a public place while suffering from scarlet fever. It is a pity that a greater penalty than this could not be meted out to persons who thus jeopardise the health and perhaps the life of their fellow-creatures.

#### SHORTHAND FOR MEDICAL STUDENTS AND PRACTITIONERS.

AMONG the students who have just commenced their medical studies there are probably some who are acquainted with shorthand, having learnt it at school. The attention of such students is specially invited to the Society of Medical Phonographers. The object of this society is to increase the practical service of shorthand to its members by publishing a monthly periodical and other shorthand medical works. Also, any medical practitioners who use shorthand and have not yet joined the society are cordially invited to do so. No skill in shorthand is necessary for membership. The annual subscription for students is 5s., for practitioners 7s. 6d. A detailed prospectus of the society will be sent on application to the honorary secretary, Dr. Fletcher Beach, 79, Wimpole-street, W.

Uncertain.—If our correspondent took the degree of M.B. London subsequently to 1887 there is no doubt that as far as qualification is concerned he is eligible for the post he mentions.

## Medical Diary for the ensuing Week.

### OPERATIONS.

#### METROPOLITAN HOSPITALS.

**MONDAY (14th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Stephenson: A Case of Congenital Distichiasis. Presidential Address:—Some Clinical Experiences of Primary Chronic Glaucoma and the Value of Iridectomy. Papers:—Mr. S. J. Taylor: Notes of a Case of Rodent Ulcer of the Cornea in a Child.—Mr. E. Nettleship: Chronic Serpiginous Ulcer of Cornea (Mower's Ulcer).

## LECTURES, ADDRESSES, DEMONSTRATIONS, &amp;c.

**MONDAY (14th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. J. Galloway: Clinique. (Skin.)

POST-GRADUATE COLLEGE (Lecture Room, West London Hospital, Hammersmith-road, W.).—5 P.M. Sir William Mac Cormac, Bart., K.C.V.O.: Opening Address.

**TUESDAY (15th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Sir W. H. Broadbent: Clinique. (Medical.)

POST-GRADUATE COLLEGE (Lecture Room, West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Baldwin: Minor Surgery.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury).—3.30 P.M. Dr. Tooth: Spinal Localisation.

**WEDNESDAY (16th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. A. H. Tubby: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (Lecture Room, West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. MacAdam Eccles: Surgical Anatomy.

LONDON THROAT HOSPITAL (204, Great Portland-street, W.).—5 P.M. Dr. Cathcart: Examination of Ear. (Post-Graduate Course.)

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL (Gray's Inn-road, W.C.).—8 P.M. Introductory Lecture:—Mr. L. Browne: The Relationship to General Medicine of the Special Diseases treated at the Hospital, also to other Diseases constituting separate Specialisms.

**THURSDAY (17th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (Lecture Room, West London Hospital, Hammersmith-road, W.).—5 P.M. Mr. Dunn: Iritis.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Dr. Still: Diarrhoea in Infants.

CHARING-CROSS HOSPITAL.—4 P.M. Mr. Waterhouse: Surgical Cases. (Post-Graduate Course.)

**FRIDAY (18th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Marcus Gunn: Clinique. (Eye.)

POST-GRADUATE COLLEGE (Lecture Room, West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Saunders: Therapeutics.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

## TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 12 6	One Year	...	£1 14 8
Six Months	...	0 16 3	Six Months	...	0 17 4
Three Months	...	0 8 2	Three Months	...	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

## METEOROLOGICAL READINGS.

## An Introductory Address

*Delivered at the Opening of the Session at University College, Liverpool, on Oct. 12th, 1901.*

By OLIVER LODGE, D.Sc., LL.D., F.R.S.,  
PRINCIPAL OF THE UNIVERSITY OF BIRMINGHAM.

GENTLEMEN.—When I left this city of my adoption, to take up closely allied but more various duties elsewhere, my regret at cutting short what might have been a life-work in the midst of tried friends was tempered by the reflection that perhaps after all I might be able to serve the city and the College from a vantage-ground of distance, and by means of experience gained elsewhere, even better than by continuing always in the same old groove of professional routine. I hope that so it may turn out. Meanwhile, I am asked by my late colleague, the indefatigable Dean of your Faculty of Medicine, to address you on this opening of session. If you had wanted a medical address you would not have come to me. If you had wanted a lecture on recent progress in physical science you would have selected some other occasion than the present. Evidently, I am expected to speak on some other topic, and I have no difficulty in guessing what that is. I have been only one year away from Liverpool, and on my return I find the atmosphere alight with two ideas, the idea of a cathedral and the idea of a university. When I left, these ideas were only smouldering, they had been smouldering for years; I could not tell how soon the breath of inspiration would reach one or other of them. I did not expect them to blaze simultaneously. The materials were there, and the spark was there, it needed only a fanning breath to start combustion and set the Mersey on fire. You will see to it that this most wholesome conflagration is not extinguished before its twin objects have been accomplished.

A year ago I confess I did not expect to find the full university ideal so prominently to the front; but any hesitation that might have been felt at urging it too hastily or inopportunistically has been removed by the resolution of your council—your college council and likewise your city council—that a university for Liverpool was a necessity and that any step towards the furthering of that object would be welcome. With the passing of those resolutions the subject leapt beyond the pale of academic discussion, it entered the arena of practical politics, and became a prominent local question of the day. I need not recapitulate the advantage of the step when it can be taken. Those who wish information on the arguments for a teaching university, and on the special advantages of a university for Liverpool, will do well to read the articles which appeared in the local press from the pen of your junior historian, Mr. Ramsay Muir. Those who wish to realise the enthusiasm which can be excited in scholars by the idea of a civic university, and the crowning glory which such an institution can confer upon its parent city, should read again the wise and statesmanlike address given a year ago to the Council of Education by my friend, Principal Dale. In that address, I find that at one time educational institutions, like certain churches before the Savoy Conference, could be spoken of as “each sailing on its own way, in the vast ocean of these tumultuating times, and holding out not so much as a light to each other.” That cannot be said of the English colleges now. The times are as tumultuating as ever, but the colleges of the country do not fail to act as beacons, each shedding an illuminating light or a warning glare on many sides. If I am asked, whence comes the illumination? I can reply, from nearly all of them in so far as they have adequate funds; and whence comes the warning glare?—it comes chiefly from those institutions which are crippled and hampered and struggling to do their best work with hopelessly insufficient means. It has not been always so, I suppose, in the history of the past. I can imagine an institution with more money than brains, but I do not find it among the university colleges. Their brains and energy and power of development are at present far in excess of their material resources. A most wholesome condition of things doubtless, but it would be good economy for the country to utilise this latent energy

of development, this locked-up or potential metabolism, and to liberate it for the benefit of the whole national organism.

But there is one caution which, for whatever my experience is worth, I feel bound to give. Do not attempt to do everything by means of endowment. Endowment for chairs there must be, large capital expenditure on buildings and equipment there must certainly be, but for current expenses I would say retain a large margin of dependence on the living generation. Keep in close touch with the community. Do not seek for independence or isolation. Encourage the leading men to take a living and personal interest in college government, and give them plenty of real power. Welcome civic control. Do not attempt to found an isolated institution for imported scholars to continue their researches, and to train youth in learning out of touch with the life and activity around them. Keep in close touch with that life and activity. In every new departure carry the community with you. An alien intrusive growth is not wholesome. No matter if it is of superior texture to the rest of the organism, if it is not properly grafted in, it is liable later to be extruded. Spare no effort to represent truly the highest ideals of the community, to raise them where you can, but never to proceed independently of them. Sometimes it may involve delay, no matter; it is better to proceed by wise and secure steps than by rapid ones; the effort of carrying the community with you will be good and educative for both sides. It is part of the function of the college thus to educate the adult community, and it will find itself surprisingly educated and raised out of academic ruts in the process. Some right steps may be delayed, but also some false steps can be avoided, and whatever is done will be done in a solid and permanent manner, in a time that is ripe, so that there shall be no going back. There is an education of the council by the senate, but there is also an education of the senate by the council; and it is by the interaction of the two that the most splendid and permanent results may be expected. I confess that the form of government of these university colleges, if well and wisely worked in accordance with the intention of the framers of the scheme, seems to me almost ideal. There have been colleges, or times in the infancy of a college—never in this one of Liverpool—when the professors have felt themselves too tightly governed, where they lacked freedom and initiative, where all control was denied them, and where accordingly they ceased to interest themselves in anything more than their own departments,—a set of detached teachers rather than a coöperative and coherent college. But the conditions never lasted long. Either reform was pressed for from outside, as at Cooper's Hill, or else a wiser course was evolved from within, as at some colleges which need not be specified. Citizens need education just as much as students, we all need education together, and a few years of college government is a splendid training.

But how are you to get annual contributions from the living? What is the mechanism? Students' fees are one source. I hope that these will not be abolished either in Scotland or elsewhere. It seems to me eminently appropriate that those who utilise an institution should contribute something to its maintenance. Abolishing fees would mean cutting off a most proper and wholesome and reasonable source of revenue, and substituting something far less natural and genuinely permanent. Who is to say how long large invested endowment will continue to bring in a satisfying interest? In a century or two that may seem an artificial and extinct source of revenue, but the contributions of the living will never be artificial or inappropriate. How, then, is it to be attained? A sustentation fund, in the ordinarily understood sense, is a trouble to the treasurer and a burden on the few notably benevolent citizens whose shoulders already bear so much, and whose bounty in order to be given to one thing must be taken from another. No, there is a better kind of sustentation fund than that. A sustentation fund to which everyone must contribute, an amount which nobody feels, and a resulting income which is really worth having. I mean a city rate, or a grant from the municipality equivalent to a rate. A ¼d. in the pound on a rental of £100 a year means 4s. 2d. Is there a single £100 householder who would resent such an annual charge as that, when he could be told that it meant £7,000 a year for the higher education of his town? And look at the capital that could then be set free for immediate development: it would be the equivalent of £200,000. One stroke, one municipal stroke, and your university might be founded. More is coming from the Government, I feel assured. This

country can no longer afford to neglect its higher education. More will be forthcoming from the Government, if more is forthcoming from the locality, the two will go together, and local support will, I expect, be the test of central contribution. It would act well all round. Every citizen would thus be contributing his mite. No citizen could any more be ignorant of what and where his university is, and it would keep us all in close touch with the life and the needs of the people. The end of my first message is:—Cultivate civic interest, and go for a city grant!

The influence of topography on development is very marked, and a city grant would have been easier to get if this college had been initially placed in a more central position, but through the action, wise or otherwise, of the late Mr. Cope this college has been placed here, for a definite reason—viz., in order to suit the medical school and the infirmary. Hence it is natural that those two institutions should have progressed with great rapidity since the college started. The infirmary has been wholly rebuilt, the medical school is rebuilding, and already in several of its departments, I hope that before long the same can be said for all, it is able to show a lead to the whole country.

It must have struck everyone connected with a college how much more thorough and complete the system of medical training is than the training thought sufficient in some other branches of practical learning. If it were like other departments there would be one professor of the subject, aided by two or three demonstrators, and there would be a two- or a three-years' course for students. The one professor would attempt to give or superintend instruction in anatomy, physiology, and pathology, in medicine, and in surgery, in forensic medicine, materia medica, and all the other branches now dealt with by an entire faculty. Fortunately the public realise that it would be unsafe for their bodies to limit the training of their future medical practitioners to a short course under one man and a few assistants. The vital importance of medical training to the community is realised, and accordingly it is entered upon in a thorough and whole-hearted way, with an adequate staff, plenty of subdivision, and exact attention to detail. But take some other profession. Take law, for instance, or engineering, or chemistry. At present one professor in each subject seems to be thought sufficient; and yet it would not be difficult to subdivide each of these great practical subjects into as many branches, or almost as many branches, as medicine. In Edinburgh, law is so subdivided, and its varieties are dealt with by six professors.

Take again commerce. There are places which are going to have a faculty of commerce. Towards such a faculty we are doubtless all feeling our way, but it seems to me that if we are to turn out men truly educated for the highest kind of commercial pursuits, if we are to raise the status of the commercial man into a truly professional position—a position which men of practical genius have already attained, and always will attain in small numbers by their own unaided abilities and strong character, if we are to raise the general level of commercial training and make it worthy of the greatness of the part which commerce plays and always has played in the history of the world,—we shall have to take a medical school as our pattern. One man cannot do it; a whole faculty is necessary, and the greater number of that faculty will, I expect, be men not holding endowed chairs, nor able to spare much time for teaching, but men really and actively engaged in the work itself; men of ability, leaders in business, who, like the prominent medical men in a city, may be willing to come down for an hour a day or a few hours a week, and give to students the benefit of their great and always growing experience. I do not say that it will be an easy matter to find men of business able and willing to do this, but I see no other way of getting it done that is likely to be half so good. I see no other way of dealing with the multifarious details and the immense variety of business transactions in such a place as this; and even now I feel that in this city we could put our finger on men who are competent to teach, and who might be willing to teach, and to fill up the outlines and fundamental principles laid down by a few endowed professors, from a sense of public spirit, and a feeling of duty which they owe to the coming generation and to the welfare of the country at large. So also some day it may be expected that, at one or other of the colleges, a theoretical faculty will arise, on lines not altogether different. And perhaps for all I know, in some places, a military and a naval college too. For all the professions, and for those

subjects which are going to be professions, the example of a medical curriculum with its five years of combined theoretical and practical training seems to me the one to follow, with modifications appropriate to special cases. A university has an advantage over a college in its ability to legislate for itself and to try educational experiments. At the present time such experiments seem absolutely necessary in education; the time is crying out for them, and the more that are wisely tried in various parts of the country the better.

One felt advantage of local self-government—viz., that each municipality can try its own experiments—is not limited to municipalities. Every city needs water and gas and electricity and locomotion and police and education, and the establishment of these things in every separate city is, or may be virtually, a valuable experiment in each case. Before undertaking such an enterprise, the city magnates pay a visit to other cities where they have already been successfully established, they are welcomed and lunched and shown round, and on their return home they proceed partly to copy, and partly to originate. The multiplication of municipalities is therefore wholly good; why should the multiplication of universities be considered bad? It is not bad at all. In other countries no one for a moment imagines it to be bad. No one even here seems to object to the multiplication of churches or of schools, nor even of colleges, but about universities there seems to be thought something dangerous. I suppose this to be due to the long period during which those altogether exceptional institutions, Oxford and Cambridge, reigned supreme in this country, and to the corresponding superstition which came to envelop a degree as with a kind of halo. Nowadays the halo does not fit. Every grade of degree exists already; the same degree is conferred upon a poll man who just scrapes through with a minimum of attainment, and upon the first-class classic or the high wrangler; and the public already know quite sufficiently well how to discriminate. Any university of the future which lets its degrees down will speedily suffer. The kind of student whom laxity attracts will soon bring upon it the desired discredit. But in saying this, I hope that the degree standard will not be of the same *kind* everywhere. I hope that we shall not all be trying to do just the same thing. There is ample scope for individuality and difference of treatment. Such diversity would be another gain from the multiplication of universities. Take this parrot cry of opponents and inscribe it on your banner; convert it into a cry for progress. Let every city become a university when it is worthy, but take good heed that it make itself worthy first. My second message is:—Multiply worthy universities.

I have spoken of the technical or professional training that is rightly undertaken in a modern university,—on the demand for this training its progress and sustenance must always be largely based,—but I wish now to say a word on one narrow aspect of the culture that will be imparted too, on the unity of learning generally, on the literary and humanistic studies that will be encouraged, and I hope enforced to some slight degree on every kind of serious student, technical and other, so that no wholly illiterate technical graduate will ever be turned out. And conversely I should hope that no cultivated man will be permitted to graduate in a condition of entire ignorance of the laws of nature. The old apologue about gilding the pill, or giving jam with a powder, or administering any nauseous drug by means of a palatable vehicle, must be a *very* old one. I found the other day that it must be at least as old as Socrates, for according to the report of an anonymous and amusingly paradoxical article in the *Journal of Education* last year, Socrates is reported to have said, while dining in an open-air restaurant with the special correspondent Xenophon before the latter left for the front, that dry bread is unsatisfying, and so is jam by itself, but that the right method is to escort each mouthful of solid nutriment with a dash of something tasty. The parable is applicable to the joint administration to students of letters and of science respectively, but it is pointed out that there seems to be a curious uncertainty as to which is the bread and which is the jam. To an untutored mind it would surely appear reasonable that the hard facts of science, linked by mathematical and other theories into a coherent whole, should constitute the main aliment and the best training of the intelligence, but that these cold truths should be enlivened and made more palatable by admixture with something of more human interest, appealing to taste and emotion,—a confection say of history and literature,—

wherewith to escort into the brain the dry facts of science. Ancient practice, however, seems to invert this untutored notion, and whereas teachers of science are expected to be lively and to show brilliant experiments, the schoolmasters who deal with human learning seem to have acquired a prescriptive right to teach their subjects by aid of books and methods of the utmost dullness, if they choose, and to be entitled to force boys to swallow them by methods which excite emotions quite other than pleasurable; so that, in fact, the boys make resolutions, and actually (as has been said) carry them out in later life, never again to open one of those beastly books as long as they live.

I wonder if there is not something wrong here. It is pointed out in the article to which I refer that whereas science may or may not be amusing or interesting or absorbing, it at any rate does involve solid fact, some of which must be known, and much more of which might be known with advantage, by every educated man. Science, in fact, if it is unattractive, is at any rate nutritious; but literature and the arts generally if they fail to be pleasing and exhilarating do lack one attribute which one would think that they ought to possess. Take the preliminary examination or entrance in arts, for instance; you see what I am driving at. I suppose it is utopian but I should like to see it attractive. There are many medical and other professional men to whom literature is a solace, and who cultivate a fine taste for it in later life; surely they must feel grateful for having had a reasonable and happy preliminary-in-arts training, and for the compulsion which made them take it at some period of their course. But the minutiae of grammar, and the technicalities of subjects in which we are never going to be anything but amateurs, are wearisome: I say this of the minutiae and technicalities of science just as much as of anything else, they are wearisome, except to those who are going to be specialists; scholars and pedants cannot tell how wearisome; these have in their minds niches and pigeon-holes gaping for these minutiae, they enjoy them and rightly enjoy them: to them they are alive and full of meaning; but to the youth with no storage capacity an accumulation of such facts is a mere rubbish heap, and his mind has the aspect of a lumber room, until after the examination when he sweeps it out. I verily believe that too much of school study, in every subject, is spent upon these dull and speedily forgotten minutiae. And at college let us discriminate between the studies which a man is going to profess and those of which he must needs have only a smattering, or what I should prefer to call a leaven. A professor of a subject cannot realise the scale or standard of the ordinary ignoramus, even of the average intelligent man. We are all ignoramuses to each other: reciprocal ignorance was largely the condition which prevailed round the senate-table when I was here, except of course in the case of the principal, who knew all subjects equally. But then we did not examine each other, we knew it was hopeless, we took each other's ignorance for granted; but we did not take the ignorance of examination candidates for granted, we set traps for their ignorance, and when we caught it we were properly indignant. I am not talking of higher studies or honours students but of elementary and general papers; these often seem to me too hard. Seldom or never can I do them.

I have been studying some school examination papers lately and I will take as an example geography. There was a paper on South Africa for a lower certificate set throughout the country. No doubt it was adapted to the teaching and to the book used; quite possibly the children answered it correctly; but there were places asked about of which a geographer to whom I showed it had never heard, and I doubt if the Colonial Secretary himself could have floored the whole paper. But now, taking geography as a kind of parable, an illustration which hurts nobody, suppose Africa, the whole of Africa, were being asked about. If the boy could sketch the position and the course of the Nile and the Congo and the Zambesi, if he knew the position and aspect of Cape Town and some of the ports and important coast stations, if he could place such countries as Morocco and Algeria and Dahomey, if he did not put the Transvaal in the middle of the Sahara—a location which some people are beginning to wish for it—he would know a good deal of what is really worth knowing and remembering, the kind of things which really are important to have in one's head, the kind of things he may remember to the end of his life although his work may lie in quite other directions. This kind of thing the boy

ought to know and know thoroughly, not in a temporary manner. Moreover, he must be taught to *understand* maps: he should understand something of how they are made, he should have some practice in actually making them. He must be able to read their meaning, as a traveller does, if possible. He must know the broad features of the surface of the earth and the great and salient facts of each country, and he should study some small interesting district with fair accuracy and completeness, as a specimen. But for the rest and for the minutiae he may refer to an atlas. Why seek to load the memory temporarily with a lot of detail? the memory declines to hold it for long, and it is a farce to ask questions on the hypothesis that such things can be really known in any useful or permanent fashion except by professed geographers. I do not mean that it is particularly hard to learn these little details and to hold them for a short time: some people find it fatally easy—I found it easy myself; but I deprecate the effort. It probably has indirect advantages, and I would not dogmatise: but when I hear talk about the General Medical Council raising the standard of the preliminary examination I get a little nervous. *Improving* the standard is all right, but raising it sounds dangerous. Very likely the recent pamphlet issued by that body is all on the right lines, I am not criticising it: so far as I remember it was on right lines and did suggest real improvements, but I do beg reformers to bear in mind the desirability of limiting the treatment of non-professional subjects to the main features and principles and outlines, to the things really worthy to be known and permanently known, and of seeing that these are known as thoroughly and pleasantly as possible, so that *taste* may be cultivated as well as memory, and a liking for subjects of general interest implanted—a wish to go further into them so soon as leisure permits. My third message then is (I trust that this part of my address is not too presumptuous—I give it with more diffidence than the rest):—Keep in touch with the schools, leave their teachers a judicious amount of freedom, let your control over school teaching be wise and cautious, and make the entrance or preliminary in arts attractive as well as compulsory.

The two functions of a university I have so far dealt with are both connected with the imparting of the inherited and accumulated wisdom and knowledge of the race—viz., (1) the awakening of interest and the development of intelligence; and (2) the implanting of such instruction and the training of such faculties as shall qualify a student for the calling by which he is to live.

But there is a third function of a university quite as important as the other two—viz., the increase or improvement of knowledge. Every improvement in knowledge tends to an increase of it, to actual discovery of new fact, but the actual attainment of discovery is not within our control, that comes sometimes unexpectedly, and seems to reward workers somewhat at random, but a steady attempt and desire to improve knowledge is within the scope of all. No one thing is known perfectly: it is remarkable how a familiar fact lights up afresh after a period of brooding on it in the light of theory and other facts. Thus it is, I suppose, that classical texts are improved, that the history of the past is deciphered, that works of literature or of art become better appreciated; and thus certainly it is that our knowledge of nature is gradually extended. The ancient formula of the Royal Society states that it exists "for the improvement of natural knowledge." I commend to your notice this word "improvement." I prefer it, as a conscious aim, to "extension." It leads to extension, but our primary aim should be improvement. Always seeking to know a thing better than we knew it before we shall find that as we get closer and closer to the heart of it, fresh and unexpected features make their appearance, appear as it were round a corner, and sometimes a whole landscape opens to the view. The guardians of knowledge *must* be improvers of it, else it begins to decay and to be lost. Constant effort is needed on the part of humanity to preserve intact even their material wealth. Leave things alone for a decade and nearly everything is rusted or moth-eaten or decayed. So it is also with the garnered fruits of learning, constant effort is necessary to preserve and improve them, and in the course of this effort discoveries will arise. The bringing down of fresh knowledge to the human race, henceforth to become part of its inheritance for ever: that is a daring and splendid achievement; it is given but to few, it is given only to those who strive early and late to improve and to increase that *of*

which they are already the custodians. A university is the corporate repository of learning, not of ancient learning only but of modern learning too; the most recently discovered fact of science there finds its natural guardians, and there it is that new facts should be born.

I commend this notion of "improvement of knowledge" to students—to every class of student. I confess that I am not enamoured of the phrase "research" when applied to the efforts of beginners. It is appropriate enough to the work of a Faraday, or of any master in science, but a beginner has no right to expect any but subjective discoveries, these latter he should constantly have in view; he should conscientiously set himself to improve knowledge, that is to say his own knowledge, to find things out for himself concerning any phenomenon that is set before him or which excites his interest, in whatever branch of learning it may happen to be; and if in the process he has the high good fortune to light upon something which his superiors consider to be of value, which is new not only to him but to them also, which is new to the world, he is heartily to be congratulated, and may feel thankful that he has received more than he is entitled to on his merits. The bare possibility of discovery awakens a kind of keen interest which nothing else can awaken, and the arousal of interest is the indispensable preliminary to real and lasting education. An atmosphere of constant effort towards the improvement of knowledge, with the accompanying stimulus of potential discovery, this is the atmosphere that should enfold every earnest student who enters the portal of a modern university.

## A Clinical Lecture

ON

### TUMOURS OF THE PAROTID GLAND.

*Delivered at St. Bartholomew's Hospital on May 29th, 1901.*

By H. T. BUTLIN, F.R.C.S., D.C.L.,  
SURGEON TO THE HOSPITAL.

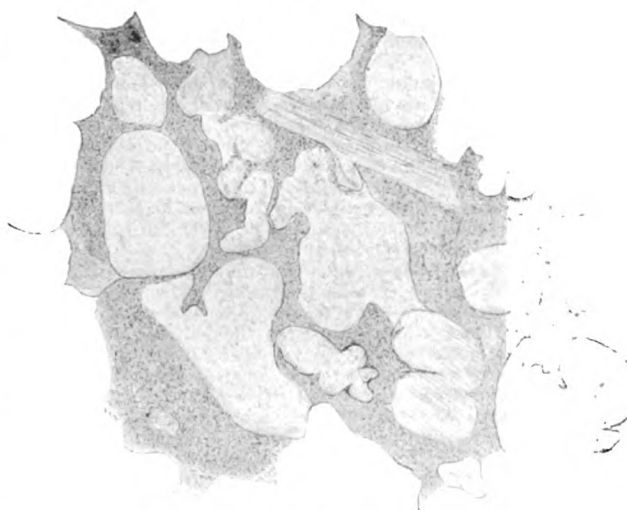

GENTLEMEN,—To-day I am going to talk, not on a subject with which I am very well acquainted, but upon a subject which has always been very difficult to me, and which I confess I am almost as much puzzled at now as I was when I first examined tumours of the parotid gland.

In the first place, let me say that tumours of the parotid gland present a very curious structure, and the structure has been either misunderstood or not understood properly—I cannot say which—by different observers during the last 25 or 30 years. As you know, the parotid gland is liable to tumours of two kinds—innocent and malignant. The innocent tumours in times past were sometimes called "enchondromata," when they were composed almost entirely of cartilaginous tissue; sometimes "chondro-fibromata," and sometimes "chondro-adenomata." At an earlier period still they were called "mixed parotid glandular tumours" or "parotid glandular tumours," "mixed connective tissue tumours," or "mixed tumours of the parotid," showing that they were composed of different kinds of tissue and that the exact composition of them was not a fixed quantity—that is to say, not nearly such a fixed quantity as it is in ordinary fibroma or sarcoma. Then people began to cut better sections of tumours and they were examined by more competent microscopists, or with better microscopes, or both combined. The men who examined them were in the habit of examining a large number of tumours of different kinds. They found a very curious structure in some of these tumours of the parotid—for example, a great part of the tumour was composed of connective tissue or of cartilaginous tissue, and then there were cells very similar to these cells which are represented here, which will do very well for the cells of a round-celled sarcoma. You see each one has its nucleus; the outlines are well defined, the cells are of

tolerably equal size and only a little larger than the cells of an ordinary sarcoma. Still, they were round and they were nucleated, and they would pass for the cells of sarcoma. But they were arranged in a very curious way. I have given you here a rough outline of a picture which I made many years ago when I used to examine these tumours. Here are the pictures of a tumour (Fig. 1 and Fig. 2) which was removed in Henry Ward in 1877, and attached are some old notes of it. These cells were arranged in this curious pattern, a sort of network or plexus, and the intervening space was filled in with either mucous or fibrous or cartilaginous tissue, as the case might be. Seeing that these round cells occupied a very large part, and seemed to be a very important part, of the tumour, histologists of that time considered that it was a round-celled sarcomatous tissue, and these tumours were called "mixed sarcomatous tumours." Sometimes they were called "alveolar plexiform sarcoma"; they were called "alveolar" owing to the spaces in them and they were called "plexiform" on account of this network of round cells.

When I wrote the first edition of the "Operative Surgery of Malignant Disease" and began to study the results of operations for tumours of the parotid gland I divided them, as I did for every other part of the body, into sarcoma and carcinoma, and then I collected together, as I had done for other parts, those I knew of in the hospital and those published in the Transactions of the Pathological Society of London and various other books and papers. I put together a number of cases of sarcoma, perhaps 29 at that time, and the results were much better than for sarcomata in other parts of the body. I found to my surprise that sarcoma of the parotid gland was a comparatively innocent disease. I wrote at that time: "The results are so much better than for almost any other part of the body that I am sometimes tempted to doubt whether there has not been a mistake in the estimate of the real nature of the tumour. Many of the most successful results are, however, reported from Billroth's clinic; many of the tumours, if not all of them, were examined by competent microscopical observers and were regarded as clear examples of myxo- and chondro-sarcoma. .... Of the most successful cases it may be shortly stated that the tumour, in the majority of them, was of small or moderate size and removed with little difficulty; it was not complicated by affection of the lymphatic glands; and that a single operation sufficed to rid the patient completely of the disease."<sup>1</sup> A doubt

FIG. 1.

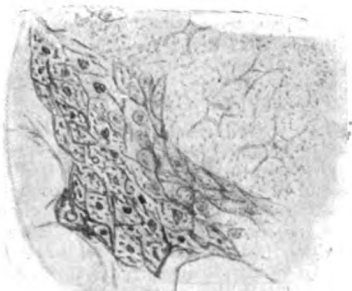

Under low power—to show plexiform arrangement.

passed through my mind whether these were sarcomatous tumours. In 1894, some years after that was written, Mr. J. Bland-Sutton published his book on "Tumours, Innocent and Malignant." In speaking of the parotid gland he made the following remark: "I am at the present time

<sup>1</sup> Operative Surgery of Malignant disease, first edition, p. 122.

unable to do more than direct attention to the chaotic condition of our knowledge regarding cancer of the parotid gland,"<sup>2</sup> and in that, I think, he included carcinoma and sarcoma. Then I began, a year or more ago, to work at the second edition of the "Operative Surgery of Malignant Disease," and when I came to the parotid gland I thought that I could probably deal with it much more readily than I had done 10 or 11 years previously. I have got the book here. I find that I looked out two papers in particular, one by a man called Nasse in 1892<sup>3</sup> and a second by

FIG. 2.

Under high power—to show oat-shaped cells like those of sarcoma, of which some of the trabeculae are formed.

Rudolf Volkmann in 1895,<sup>4</sup> and in these two papers an entirely different view is expressed of the nature of these tumours. These gentlemen—and I think on very good ground—express the opinion that these so-called myxo-sarcomas and fibro-sarcomas and chondro-sarcomas of the parotid gland are not sarcomas at all, but that they are endothelial tumours and that the networks and plexuses of round cells are endothelial cells derived from the lining of the lymphatics and the blood-vessels. That assumption would, of course, cut out nearly all the cases of sarcoma which I had included in the 29 cases. This view seems to have gained ground amongst pathologists, with the result that not only are the sarcomas of the parotid gland very much diminished in number, but sarcoma there has been almost suppressed, and some pathologists are inclined to say that there is no such thing nowadays as sarcoma of the parotid gland. And, further, there is great doubt in the minds of some of these gentlemen whether there is such a disease as carcinoma of the parotid gland. That shows how, in such a study as microscopical anatomy, there is room for an enormous difference of opinion, and how pathologists may at one time be of one opinion and a few years later they may hold a totally different opinion, or two schools of pathologists at the same time may hold, one set one opinion, and another set another opinion, as to the meaning of the structure of a disease. So when I had to deal with this question I found that I could not deal with it in the same way as I could deal with the tumours of other parts of the body, dividing carcinoma from sarcoma, and I was obliged to put them all together as malignant disease of the parotid gland, and to try to find out what happened to patients who really bore the mark of their tumours being malignant disease.

To-day I have come to the conclusion—and you will presently see how perplexing the subject is—that the old sarcomata should be called endotheliomata mixed or simple, and that they are quite innocent tumours, because they are generally encapsuled. They do not always shell out easily, because they are embedded in the substance of the parotid gland; but there is no glandular enlargement—they have no aspect of malignancy, either clinically or microscopically. I thought that I would like to show you some of the patients on whom operations had been performed, so I sent for four patients and three of them have come. One of them is a man who has only just left the hospital and the wound has not healed. His was a case of malignant tumour without a doubt. Another patient

is a woman on whom I twice operated, the first time in 1897, and removed a not very innocent-looking tumour which was said to be myxo-sarcoma with glandular tissue. It may have been an endothelioma. I operated upon her for a very bad recurrence in November, 1898, and I removed almost the entire parotid gland. I did not limit myself to removal of the tumour, because it was deeply embedded; it had spread so deeply into the structures about the parotid gland, and it seemed very malignant, and I felt that I had not taken it all out. She had facial paralysis after the operation, and I thought that I had cut the facial nerve through, but to-day you will see that she bears signs of paralysis of the lower part but not of the upper part of the facial nerve, and that she has only a very small recurrence of the tumour, and it does not bear any serious characters. If she will come into the hospital, as I think she will, I will remove it for her, and I shall be more hopeful of her case than I was before. Yet it is recorded as a case of malignant disease of the parotid gland on the second operation. Then comes the third case, a woman, 25 years of age. In 1898 she was operated upon, either at the end of October or at the beginning of November. I took out a small tumour, two inches by one and a half inches, from the parotid gland. There was no trouble with the facial nerve; the tumour was nodulated and moveable. Mr. F. A. Rose has copied from the notes that the skin over it was natural. At the operation the tumour was well encapsuled, easily dissected out, and when it was sent up for report it was described as a mixed-tissue parotid tumour—what I should now call an endothelioma. I sent for her to come up to show how nicely one can take out a tumour of that kind from the parotid gland, so as to leave a very small scar; there was no effect upon the facial nerve, and, in fact, it was what I considered to be a very nice case of surgery. Now that she is here I feel as if I should like to suppress her case, for she comes with a worse recurrence than the other patient. The tumour is attached to the scar and fills up the space between the mastoid process and the jaw, and so far from my being able to display to you my skill as a surgeon and the innocence of endothelioma of the parotid gland, her case illustrates neither one nor the other, and I am more puzzled than ever at the pathology of parotid tumours. The primary tumour was not a big tumour. I apparently took out the whole of it without difficulty, and I thought it to be perfectly innocent, while the microscope proclaimed it to be an endothelioma. Yet within four months of the operation it began to grow again and now it is as large as the tumour which was first removed. [Cases shown.]

The next question with regard to these tumours of the parotid gland is the effect on the facial nerve of innocent and malignant tumours respectively. On that point there is not absolute agreement, but there is a tolerable agreement amongst surgeons and pathologists that innocent tumours of whatever size seldom or never produce facial paralysis. Billroth pointed out some years ago that he believed that if a tumour of the parotid gland were associated with paralysis of the facial nerve that tumour would prove to be a carcinoma; he did not think that the innocent tumour or sarcoma produced paralysis of the facial nerve. But of course he had in his mind these tumours which I have spoken of which we do not now regard in the light of sarcomatous tumours. True sarcomas probably do affect the facial nerve. In proof of this I may mention a case which I had under my care in this hospital some two or more years ago. It was that of a female, 20 years of age, who came to the surgery with a small tumour of the parotid gland, in character very much like the tumour of that young woman who has just gone out. Although the tumour was moveable and perfectly circumscribed and apparently inclosed in a capsule, and although it had all the characters of an innocent tumour to the touch, yet it was associated with a slight paralysis, or rather paresis, of the branches of the facial nerve going to the orbicularis oculi. I took her into the hospital and we discussed her case in my class. I drew attention to the paresis of the facial nerve and then we discussed whether the tumour was likely to be innocent or malignant. I said that I had never seen an innocent tumour of the parotid gland which was associated with paralysis or paresis of any part of the facial nerve. So we come to the conclusion that in this case, in spite of the general innocent characters of the tumour, in all probability it was a more or less malignant tumour. I dissected it out and found it to be

<sup>2</sup> Tumours, Innocent and Malignant, p. 248.

<sup>3</sup> Langenbeck's Archiv, Band xlv., p. 233.

Deutsche Zeitschrift für Chirurgie, Band xli., p. 1.

inclosed in a perfect capsule, but the facial nerve ran right along the upper part of it and was just caught in the capsule, and hence the paresis. I dissected the tumour out with very considerable care and there was no further paresis or paralysis of any other branch of the facial nerve. The tumour was examined microscopically and was found to be a well-marked example of spindle-celled sarcoma. So I expected this patient to come back in a short time with a recurrence of the disease, and I thought that in all probability the recurrence would be of the upper part on account of the obligation which I was under to keep close to the tumour to avoid cutting through the facial nerve, which is a serious matter for a young person. She did, indeed, come back to the hospital two years afterwards with a tiny recurrent tumour, but instead of its being in the upper part it was in the lower part of the parotid gland, quite away from the place where I thought I might have left part of the capsule. I cut the recurrence out for her. It was circumscribed and moveable and again bore the characters of a spindle-celled sarcoma. That occurred two or three years ago, so that at any time we may have a visit from her, and then I may find that she has recurrence of the disease.

Curiously enough, in looking into the accounts of the surgery of parotid tumours a good many years ago I found that Billroth again, in his Clinical Lectures, says that although he has never seen paralysis of the facial nerve as a result of pressure of an innocent tumour or sarcoma of the parotid, he has seen it very frequently as a result of operations for the removal of these tumours; from which I judge that, believing the tumours to be malignant, he himself was in the habit of removing them very much more freely, and a larger portion of the parotid gland and tissue around, than we have been doing in this hospital. I cannot remember paralysis of any part of the facial nerve after an operation for removal of an innocent tumour, and I should speak similarly for the practice of my colleagues which I had an opportunity of watching when I was registrar here. Every surgeon here who had a parotid tumour to remove dissected it out with great care and I do not remember a case in which the facial nerve was wounded in the operation, and I wondered whether that was not due to the influence of Sir William Fergusson who was one of the greatest surgeons in London 40 years ago. A distinguished operator told me that when he himself was quite a young man and just beginning to get into practice a lady came to him with a small tumour of the parotid gland. She was a person in society, young and good-looking, and she was naturally very anxious about her personal appearance. He said to her, "Well, madam, you can have it removed." She said, "What will be the effect if I do have it removed?" He said, "I think you will do very well." She said, "What will be the effect on my appearance?" He said, "Well, it is quite possible that the facial nerve may be wounded in the course of the operation." As to that she asked, "What effect will that have upon me?" He replied, "Well, I am sorry to say that you will not be able to close your eye and your mouth may be a little drawn to one side." She consulted other surgeons, and among them Sir William Fergusson. She said to him, "What about this tumour?" He said, "Well, you can have it out." "But what about the facial nerve?" "The facial nerve? If anybody is fool enough to look for it he may wound it, but if you have it out the surgeon will not look for the facial nerve." That is the course we have adopted in this hospital. I read of the different relations of the facial nerve to innocent tumours of the parotid gland, how in one case it runs in front, in another case behind, and in another case right through the tumour. I have never seen the facial nerve running through an innocent tumour of the parotid, and I never have dissected the facial nerve from the surface of one of these tumours. I never have seen it underneath because I have not looked for it. I believe that that is the case with nearly all innocent tumours of the parotid gland. Keep close to the capsule and shell the tumour out carefully, and do not get straying about to find out the relations of the tumour to surrounding parts.

I must confess that the surgery of malignant tumours of the parotid gland here, both in my own practice and in that of everybody else, has not been, as far as I know, at all successful. I have removed a tolerable number of these tumours, possibly more than my share, here because I get a good deal of tumour surgery in the hospital. I have generally dissected the tumour out, keeping close to its capsule and being very cautious not to wound the facial

nerve if I could help it, on account of the disfigurement, and not to run into the vessels which lie in and beneath the parotid gland. I was of opinion that, taking into account the liability of the neighbouring lymphatic glands to secondary infection, and seeing what difficulties there are in a free removal of these malignant parotid tumours, the surgery of them must necessarily be very unsatisfactory. I was of that opinion until I began to write the second edition of my book, and on looking up the literature of the subject I came upon a paper by Mandowsky,<sup>5</sup> Professor Schüller's assistant, saying that Professor Schüller had made up his mind that the surgery of malignant tumours of the parotid gland was not as good as it ought to be because we did not deal with the cases in the same fashion as we dealt with malignant tumours of other parts of the body—of the breast, for instance. Professor Schüller had been acting on this for some time past, and had been removing not merely the tumour but had taken out the parotid gland by a regular set operation, clearing out the gland with the tumour in it and not examining too closely the tumour or the surrounding parts. He had been prepared for paralysis of the facial nerve, which is generally inevitable in complete removal of the parotid gland, but he entirely disregarded this, and he thought that disfigurement was a matter of no consequence compared with freedom from the disease. He devised an operation by which he laid back the skin, as I have done here, and instead of dissecting from below, as most people would do, to get hold of the great vessels and secure and tie them at an early period of the operation he began in front, raising the skin up off the masseter muscle and the glandular tissue. Finding the limits of the gland in front he dissected it out from the upper and front part, and secured the vessels by double ligatures as they were divided. He found that it was easy, or at all events not difficult, to clear out the entire parotid gland, of course with the facial nerve and the tumour. He found that as the operation proceeded the tumour and the gland, instead of having to be raised up in order to get at the deeper parts, gradually fell backwards, and so the operation was rendered more easy the further he got. I have practised this method on two or three occasions and I did so for this man whose wound is not yet well. Some of you saw the operation and you saw that the parotid did not fall backwards, but stuck to everything, and that I removed the disease with very great difficulty. The glands were affected at the lower part and I do not think that I entirely removed them. In fact, the disease was so extensive and the bone was so involved that I am sure that I did not take the disease completely out.

I am afraid that neither this nor any other operation will be of use against advanced malignant disease of the parotid gland. The limits of the gland are over-passed and the neighbouring glands are already affected. But against malignant disease at a much earlier period Professor Schüller's suggestion appears to be very reasonable. If you practise it by-and-by, as some of you may do, I am almost disposed to advise you not to study too closely the anatomical relations of the parotid gland. Your business is to keep close to the capsule which incloses the parotid gland and to take it away with all that it contains, including the facial nerve and, of course, the malignant tumour. While considering this lecture it occurred to me that I ought to make myself familiar with the neighbouring anatomy and that I would impress on you the number and nature of the parts which are in relation with the parotid gland. As I had forgotten some of them I took down Gray's "Anatomy" and read them through, and I confess that I was aghast at the perusal and wondered how I could have dealt with so many and such important structures and left the patient still alive. Yet here he is, and the other patients on whom I have performed a similar operation made quite as good a recovery. So I determined to advise you to do what I have just said: keep close to the capsule of the gland and secure and tie the vessels as, or even before, they are divided, and not to trouble too much about their names and quality. Make a large incision, and a second cross-incision if you choose, and expose the field of operation in such a manner that you can see well where your knife is working, and always remember that you are dealing with a terrible disease, and that risk of life and disfigurement is quite justifiable in the attempt to remove it thoroughly.

I wish I could give you some good rules for the early diagnosis of malignant tumours of the parotid gland. The

<sup>5</sup> Aertzlicher Praktiker, 1894, Nos. 32 and 33.

diagnosis is easy when the disease is advanced, but it certainly is not easy when the tumour is still well within the parotid gland. This is one of the points to which attention must be directed in future.

Now, gentlemen, I am conscious that this lecture is very defective. It is defective in knowledge of the diseases of which I have been treating and it is defective in knowledge of how to deal with them best by surgery, particularly the malignant diseases; but I chose this subject because every now and again I like to lecture on something which I do not know well, in order to review the subject and to see what new lights it presents, and if I am asked by any one of my past house surgeons or by somebody who is about the hospital to recommend them a piece of special work I am sure that nobody could do better work or work which is more likely to bring credit to himself and to surgery than he who engages in work upon these tumours. Let him take the whole subject up afresh and work from both a clinical and a pathological standpoint. The material in this hospital is very rich. He will find here a most interesting series of tumours, including one melanotic tumour of the parotid and one partly melanotic tumour of the same region. He will find also sections of a certain number of these tumours in the microscope box upstairs, and he will find a much better account of operations and the connexions of the tumour than he would have done years ago, particularly in my own wards, where the notes have been taken with considerable care by my dressers. He can search out patients and can trace them, and he can also use my private notes and drawings of parotid tumours removed in this hospital many years ago when I was surgical registrar. I wish that I could persuade somebody to take this up and to give some months to it. It is worthy of being the subject of a treatise for a degree at one of our universities; but I think it is worthy of something more than that: it might make a very good monograph—a monograph founded, I think, on extraordinarily rich material.

## DEVELOPMENTAL (MYELOGENETIC) LOCALISATION OF THE CEREBRAL CORTEX IN THE HUMAN SUBJECT.<sup>1</sup>

BY DR. PAUL FLECHSIG  
OF LEIPSIC.

(Translated for THE LANCET.)

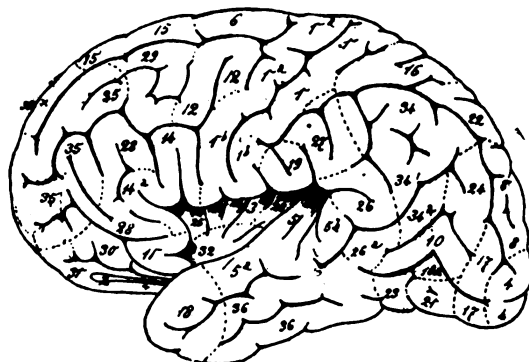

### I.

THE following remarks are founded partly upon researches carried out some time ago and partly upon unpublished new researches undertaken on the human subject exclusively, and therefore of especial value in this respect.

In the cerebral convolutions, as in all other parts of the central nervous system, the nerve-fibres do not develop everywhere simultaneously, but step by step in a definite succession, this order of events being particularly maintained in regard to the appearance of the medullary substance. In the convolutions of the cerebrum the investment with medullary substance (myelinisation) has already begun in some places three months before the maturity of the foetus, whilst in other places numerous fibres are devoid of medullary substance even three months after birth. The order of succession in the convolutions is governed by a law identical with the law which I have shown holds good for the spinal cord, the medulla oblongata, and the mesocephalon, and which may be stated somewhat in this way—that, speaking approximately, equally important nerve-fibres are developed simultaneously, but those of dissimilar importance are developed one after another in a succession defined by an imperative law (Fundamental Law of Myelogenesis). The formation of medullary substance is almost completed in certain convolutions at a time when in some it is not even begun and in others has made only slight progress, so that the convolutions are divided at certain periods of

age into regions which are (1) well provided with medullary substance, (2) scantily provided with medullary substance, (3) altogether devoid of medullary substance. Thus the convolutions come into existence sharply circumscribed areas differing in the stages of development of their elements<sup>2</sup> which I call myelogenetic cortical areas. These fields are constant in arrangement; they repeat themselves in essentially the same position and extent in all individuals of approximately the same age. The contours do not change perpetually with the progress of the medullary investment, but show during a certain period the same type, a fact which obviously depends upon the general character of the myelogenetic differences. It has been said (1) that the formation of medullary substance spreads from certain points in the cortex—to some extent in concentric rings—over the surface (Vogt), or that the order of succession in which the nerve-fibres receive medullary substance is in relation to the diameter of the fibres (Vogt), or (3) that this order of succession is in relation to the position of the blood-vessels (von Monakow). These opinions, however, are generalisations from accidental phenomena, and when treated as a whole they are found to be ill-supported and totally useless from a scientific point of view. (Fig. 1 and Fig. 2.)

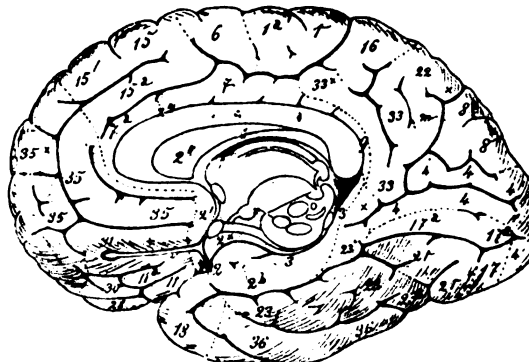

FIG. 1.

Cortical areas on the external surface of a cerebral hemisphere.

In my first memoir on the subject<sup>3</sup> I estimated the number of the myelogenetic cortical areas at 40. Further researches have shown that some of these must be combined into one, so that I at present distinguish only 38.<sup>4</sup> I find

FIG. 2.

Cortical areas on the internal surface of a cerebral hemisphere.

<sup>1</sup> The protoplasmic processes of the ganglion cells are also formed in different areas at different times. This is another instance of periods of time arranged in conformity with a natural law.

<sup>2</sup> 1898. *Neurologisches Centralblatt*, No. 21.

<sup>3</sup> In my report to the Paris Congress held in 1900 I pointed out that the number 40 must be taken as a provisional estimate. The diagrams of my cortical areas which Hitzig gave in the *Comptes Rendus* of the Section for Neurology (Pl. II.) are useless. They are neither copies of my drawings of 1898 (for here the areas nowhere show contours) nor of any other illustrations whatever that have been published by me. They are simply of the nature of misconceptions, enlarged reproductions of private communications (rough sketches) which being incomplete were not intended for publication and which in the form given to them by Hitzig can only lead to confusion.

<sup>4</sup> A paper read at the International Congress of Physiology at Turin. Owing to the operation of a time limit in the delivery of the address some passages here shown had to be omitted from the paper as originally written.

all to denote the areas simply by numbers (1 to 36) in accordance with their respective places in order of development, and therefore wholly chronological. In order to present a comprehensive view, and having regard to differences of a general nature, I have classified them in the three following chronological groups: (1) regions of early development (primordial zones); (2) regions of intermediate development (intermediary zones); and (3) regions of late development (terminal zones).

As the process of myelinisation presents no distinct intervals, the fixing of the limits of these groups is to some extent a matter of individual opinion; there are not as yet any definite landmarks to go upon. In my first memoir I assigned to Group 1 the areas which showed a comparative preponderance of medullary substance at birth at full term—i.e., the areas numbered 1 to 8. Further investigations have convinced me that as a rule the number of areas in which myelination has at least commenced before birth at full time is greater than this, including as a maximum the areas as far as No. 20, but sometimes only those as far as No. 12. The extent to which the medullary substance has spread at the time of full development of the fetus is therefore not available in all cases as a principle of classification. Nevertheless, the areas numbered from 1 to 10 have this in common, that in full-term fetuses the formation of medullary substance has, as a rule, not only begun in these areas but has advanced so far that it is perceptible to the naked eye. I accordingly reckon Group 2 from area No. 11 onwards. Under Group 3 I some time ago included those areas in which the formation of medullary substance (birth at full time being taken for granted) does not begin until after the completion of the first month of the child's age. This applies, as a rule, to the areas numbered from 32 to 36, occasionally, also, to No. 31; but this last-mentioned area appears to me to present individual variations of a special kind.

## II.

The general significance of the myelogenetic localisation of the cortex may be put into words as follows. Every area possesses a special anatomical position and, therefore, also a special functional importance. For a great number of the areas this can now be absolutely proved. [The objection that the recognition of 36 different "organs" in the cortex means a falling-back to the phrenology of Gall, and other objections of a like kind, may be met by a simple reference to the fact that it was the myelogenetic parcelling-out of the surface of the brain which for the first time provided tangible and comprehensive anatomical data for the scientific solution of the questions involved, and which revealed points of difference that had not up to that time been even suspected.] The average size of a cortical area (about 20 square centimetres—three and a quarter square inches) is very considerable when compared to the much smaller dimensions of the medulla oblongata with its many centres.

Anatomically, the areas forming Group 1 (primordial zones) are distinguished above all by their great richness in projection fibres (fibres leading to and from sub-cortical centres). This group contains the points of entrance of all the channels conveying sensory impressions to the cortex. Every sensory peripheral end-organ has corresponding to it in the cortex a well-defined region of early development (primordial zone)—the cortical sensory centre or sensory area. Area No. 2 is the olfactory centre, No. 4 is the visual centre, No. 5 is the acoustic (cochlearis) centre, and so on. From pathological and other phenomena area No. 1 may be regarded as the end-organ, especially of the posterior columns of the spinal cord and consequently of the posterior roots; the nerves of the skin and muscles seem to be represented here side by side. For many primordial zones (as for instance the gyrus subangularis No. 10) it is for the present unknown whether they are in relation with any peripheral end-organ at all.

The individual sensory areas are separated from one another by wide tracts of cortex (intermediary and terminal zones) in which sensory fibres cannot be followed up. Moreover, the known motor fibres originate in and immediately beside the regions of early development (primordial zones), such as the pyramidal tract in No. 1, the motor part of the inferior fornix in Nos. 2 and 3, the inner fasciculi of the ventral part of the cerebral peduncle (pes or basis or crura pedunculi) in Nos. 16, 6, 12, 14, and 15. Only with respect to the external fifth of the pes pedunculi

(column of Türk) is there a controversy as to the cortical regions of origin (Nos. 5 and 36). From No. 4 a set of fibres can be followed (in secondary degenerations and in newly-born infants) up to the central medullary substance of the anterior corpora quadrigemina; these fibres are lost in the "secondary" visual radiation (Flechsig). Therefore to every sensory path there corresponds a motor (corticofugal) tract. One may speak, therefore, of conjugate tracts or columns (Strangpaaren). With regard to their position within the corona radiata, they in general follow the law that corticopetal lines of communication are placed laterally with respect to the centrifugal ones.

In the primordial zones the corticopetal and corticofugal fibres do not mingle uniformly. It may be specially remarked with reference to No. 1 that the tactile radiation passes over for the most part into the posterior central ascending parietal convolution and only with a few fibres into the anterior central, whilst the undoubtedly motor pyramidal tract originates to a great extent from the anterior central ascending frontal convolution and to a less extent from the posterior one. Area No. 1 is therefore composed of a preponderating sensory and a preponderating motor division. A purely sensory or a purely motor area cannot be outlined anywhere. The auditory sphere (No. 5) to which fibres lead from the internal corpus geniculatum and thalamus, which may be denoted as the auditory radiation (and eventually as the cochlearis radiation)<sup>1</sup> according to my researches (in cases of secondary degeneration), sends fibres into the column of Türk—fibres which to all appearance terminate in the pons and convey corticofugal impressions. Whether they are to be considered as motor fibres is not quite decided. To all appearance their origin projects somewhat beyond the region of the auditory radiation and extends also to the part of the second temporal convolution hidden in the first temporal furrow; it is therefore a cortical region immediately adjacent to the auditory sphere. It is very questionable whether the convex part of the second and third temporal convolutions belong to this zone. In the cortex they lose the arrangement of the fibres which is characteristic of motor regions, whilst this type is very prominent in the auditory sphere and immediately beside it in the second temporal convolution. Therefore in the event of the columns of Türk fulfilling motor functions (motions of the body and head in consequence of auditory impressions?), it will have to be admitted with respect to the auditory sphere that here a motor and sensory area are united in such a way that they partly coincide and partly perhaps do not coincide. Here, as in the cortex generally, an entirely motor or entirely sensory area is not recognisable.

In the regions of late development and in most of those of intermediate development the corona radiata is not represented. The projection fibres therefore undoubtedly diminish in number here in comparison with the primordial zones. This is the case not only in newly-born children, but also in children of the age of four, five, seven, and eight months. It has been said that the scanty occurrence or complete absence of the projection system in the cortical areas of late development is quite an illusion, and that the corona radiata appears here only at a later stage, but this objection has little to support it. At no period of age do I find clearly differentiated fasciculi of the corona radiata. Some projection fibres may be recognised in the intermediary zones and occasionally also in the terminal zones, but they sink into insignificance in presence of fibres of a different kind.

The normal adult brain presents conditions too complicated to permit of positive opinions being arrived at. But two of the most important projection systems (the fasciculus longitudinalis inferior and the cingulum) have been declared to be association systems, and the descriptions of the brain in the most recent articles by von Monakow, Déjerine, and others propagate these quite incomprehensible errors as if they were established facts. Nowhere in adults do I find fasciculi of the corona radiata which might not occur in children aged three and a half months, the children having been born at full time. In them the extension of the corona radiata can be clearly seen, and it is plain that the convolutions which contain abundance of projection fasciculi have others opposite to them in which it is hardly possible to find one such fasciculus.

It is also a complete mistake to assert that secondary

<sup>1</sup> The position of the vestibularis conducting fibres in the corona radiata is not yet determined; indeed it is by no means proved that the semicircular canals are in connexion with the cortex of the cerebrum although it is extremely probable.

degenerations in the adult human subject prove the contrary. If everything that has hitherto been published in support of this view is brought together it will be found that not even half a dozen cases are recorded which supply incontestable data, and of these the majority are referable to two areas, No. 1 and No. 4. For the other areas neither von Monakow nor Déjerine has quoted cases which could really decide the question in terms of the corona radiata. I wish here to make this statement only for the last three terminal zones, since Déjerine has said that he has specially investigated uncomplicated cortical lesions, even quite superficial ones, of these regions, and has always found fasciculi of the corona radiata in a state of secondary degeneration. But taking the case of area No. 36, in the alleged uncomplicated lesions of this area there is always accompanying derangement of either the first temporal convolution (acoustic sphere) or of the visual radiation. With regard to area No. 35, Déjerine describes what he calls an uncomplicated superficial lesion and deserves our thanks for having given a drawing which enables an idea to be formed of its extension in the direction of depth. From this it is evident that in reality the primary softening of the first and second frontal convolutions has not only reached the corona radiata of the gyrus fornicatus traversing the frontal medullary substance but has partially disorganised it, and it is anything but surprising that secondary degeneration of the anterior pedicle of the optic thalamus should be transmitted in the thalamus to regions the connexion of which with the gyrus fornicatus can be recognised from a study of the history of their development. How little all these drawings prove is abundantly plain from the fact that in the same case an identical degeneration is found in the optic thalamus on the opposite side, but is here due to a focus of disease "in the third frontal convolution."

Finally, the case of superficial disorganisation of the gyrus angularis (area No. 34), a lesion which is in this instance alleged to be uncomplicated, is in reality not concerned with this convolution exclusively, for areas No. 26, No. 27, and No. 5a are also disorganised. Neither is the softening limited to the cortex; on the contrary, it has penetrated to the optic radiation (corona radiata), so that on every sound principle there is no reason for bringing the secondary degeneration found in the corona radiata and optic thalamus specially into relation with the degeneration of the cortex of area No. 34.

Moreover, the cases of foci of subcortical softening, which have served for investigations of secondary degeneration in the corona radiata, entirely fail to support the opinion that the terminal zones No. 34 and No. 35 are provided with a corona radiata. In a case described by von Monakow, in which there was a focus of softening in the thalamus opticus with fibres of the corona radiata in an alleged state of secondary degeneration present in the whole of the upper part of the cerebrum, not only was the examination made by a quite inadequate method (the use of carmine) but the case was, moreover, so greatly complicated by the occurrence of numerous milary foci in the parieto-occipital lobe that definite conclusions seem to be impossible. Everyone who has been to some extent engaged in the investigation of milary foci of softening knows that secondary degenerations may proceed from each one of them. The account of the finding of degenerated fibres (and cells) in area No. 34 (?) given by von Monakow says nothing as to the origin of these fibres. In like manner a case recently described by Proft (discovery of Marchi's strata in all three frontal convolutions, &c., in a case of hæmorrhage in the thalamus) is so ambiguous that it cannot serve as a proof of the presence of a corona radiata in area No. 35. For instance, in it both pyramids showed degeneration. If Proft's interpretation is accepted it would therefore have also to be inferred from this observation that both pyramids of the medulla oblongata are in relation with the thalamus opticus of the right side—a thing which is most improbable.

In the present state of knowledge on the subject of secondary degenerations I think that it is extremely unscientific to attempt to infer that "the pathological method" has absolutely proved that all the convolutions of the cerebrum are equally provided with a corona radiata. In conclusion I ask, Why is there no doubt as to the central convolutions and the visual sphere possessing an exceedingly effective corona radiata? Why cannot it be demonstrated in the terminal zones?

### III.

Clinical observations of the symptoms produced by lesions of various cortical areas give results which agree very satisfactorily with those obtained by a study of the developmental conditions of those areas. Disorders of the motor and sensory functions are observed only in lesions of the primordial zones. The motor zone delimited by Charcot coincides with area No. 1; the zone defined by Henschen (the most reliable worker in this field), lesions of which always interfere with vision, coincides with No. 4, and so on. Of localised symptoms which occur in lesions of the intermediary and terminal zones the only known forms are some that involve (1) interference with speech (alexia, optic aphasia, sensory amnesic aphasia, &c.), and (2) partial amnesia (optic, for example). The time to localise these symptoms more definitely has not yet arrived. The question will ultimately reduce itself to this—whether the structures concerned in these obviously preponderating association disorders are the intermediary and terminal cortical zones (i.e., their ganglion cells), or are only deep-seated association systems (i.e., nerve-fibres), as Wernicke and others suppose. I consider it, however, to be extremely unsettled, and it will be impossible to come to a satisfactory decision without a more intimate acquaintance with the whole mechanism of association—namely, of the nerve-fibres and the connexions which they form between the different areas.

From my observations on the child I am led to believe that the opinions which have hitherto been held regarding this mechanism are erroneous, at least so far as concerns the so-called long association system. The fibræ arcuatae which unite every two neighbouring convolutions are found between all the areas which immediately adjoin one another. Areas which lie further apart are united by long tracts, and it is to be observed that their anatomy is as yet incomplete in the highest degree. All the areas with long tracts are by no means in effective connexion. The areas differ with respect to the corona radiata and they also differ in a most extraordinary manner with respect to the long association systems. The terminal zones are the richest in them; they are the endings of the long association systems. On the other hand, no long association system is known which connects two primordial zones that are to be regarded as sensory centres. The fasciculus longitudinalis inferior, which is always quoted as an example of this, is in actual fact a projection system, the real optic radiation, the line of transmission of optic stimuli from the external corpus geniculatum to the visual centre in the cortex, and this can be demonstrated in the newly-born so conclusively that all objections to it must fail. If a visual and an auditory impression meet one another anywhere in the cortex of the cerebrum, this can only happen through the instrumentality of the intermediary and terminal zones. If the mutual interference of the stimuli is a preliminary condition of the association of their mnemonic impressions, the cortex of the intermediary and the terminal zones will be indispensable for this purpose also. They are therefore association centres; and this view is strongly confirmed by the clinical observation that in lesions of the region lying between the visual and tactile spheres it is association troubles that occur, the best known of which is sensory alexia.

The objections which have been raised against these views on the grounds of comparative anatomy, experimental observation, and the study of the successive phases of development are not very weighty. If the development of the medullary substance is studied in the lower animals it must not be forgotten that they are without exception much less favourable for the purpose than the human subject is. Here it is a fact of primary importance that in the lower animals the process passes through its stages much more quickly than in man—in the cat, for instance, in about one-fifth of the time. All the phases of the development are brought much closer together. The number of the areas in the cortex is considerably less (in the dog Dr. Döllken could hardly reckon 20), and the size of the areas of late development is much greater in the human subject than in the lower mammals, so that in the human subject not only do all the points of difference continue unchanged over far larger spaces of time, but they also take much clearer and more distinct shape. The fundamental laws of development come better into view in the human subject, in like manner to the degree in which the human intellect excels that of the lower animals.

## ON THE PROTECTIVE SUBSTANCES OF IMMUNE SERA.

By E. W. AINLEY WALKER, M.A., M.D. OXON.,  
RADCLIFFE TRAVELLING FELLOW, UNIVERSITY OF OXFORD.

(From the Bacteriological Institute of Berne and the Pathological Laboratory of the University of Oxford.)

## PRELIMINARY COMMUNICATION.

THE experiments on which the following arguments are based were made originally in the Bacteriological Institute at Berne during the early months of the present year.

1. If the M. L. D. (minimum lethal dose) of a given bacterial culture be determined and the dose of immune serum necessary to protect against this M. L. D. be called its serum equivalent, it has been observed that if an animal be now given two M. L. D. and two serum equivalents it is not protected but dies from the infection. This has been explained as due to a deficiency of addiment in the animal concerned, but in reality it is only due to a deficiency in the amount of immune body given in the immune serum.

For if  $d$  be the M. L. D. and  $e$  the largest dose of the bacterium found not fatal,  $s$  the dose of serum necessary for protection in the first experiment with one M. L. D., it follows that since the animal can itself protect against a dose of  $e$  the serum  $s$  was protecting only against  $(d-e)$  of the bacterium when one M. L. D. was given. When, therefore, we proceed to give two M. L. D. we require serum protection against a dose of  $2d-e$  and this requires  $\frac{2d-e}{d-e}s$  of the

serum. Similarly three M. L. D. require  $\frac{3d-e}{d-e}s$  serum and

four M. L. D. require  $\frac{4d-e}{d-e}s$  serum. Experimentally, if serum be given according to this formula the animals are found with the bacillus used—the bacillus typhosus—to be completely protected up to and including the fourth M. L. D., and only after this point is passed does a deficiency of addiment appear, as may be seen below, where the serum-equivalent of one M. L. D. is called the serum unit,  $d$  being 0.075 of a given culture,  $e$  0.05 of the same culture, and  $s$  0.025 cubic centimetre of immune serum per 100 grammes of guinea-pig.

Guinea-pig	1	given 1 M.L.D. and	1 serum unit; recovered.
"	2	" 1	" " died in 16-18 hours.
"	3	" 2	" " units; recovered.
"	4	" 2	" " died in 18 hours.
"	5	" 3	" " recovered.
"	6	" 3	" " died in 14-16 hours.
"	7	" 4	" " recovered.
"	8	" 4	" " died in 18-20 hours.
"	9	" 5	" " died in 14 hours.
"	10	" 5	" " " "
"	11	" 6	" " " "
"	12	" 6	" " " "

In another series of experiments made in Oxford with a more virulent variety of the bacillus typhosus the deficiency of addiment appeared at the fourth M. L. D. In working with the immune sera it is therefore necessary to employ the formula above arrived at in order to determine accurately the amount of serum which contains the quantity of immune body required for any given multiple of the M. L. D. of the bacterium concerned.

2. On the observed deficiency of addiment in experiments with multiples of the M. L. D. of a bacterium Professor Ehrlich founds a theory of the specialism of the addiment to the species of animal in question. He holds that an animal can only make use of its own addiment or of that of others of its own species, and hence endeavours to explain the fact that immune serum does not supply the lack of addiment observed. But this view is out of harmony with the experimental facts. Thus Wassermann found the addiment of fresh ox serum satisfactory to guinea-pigs and to the immune serum of dogs which was used for their protection. Ehrlich and Morgenroth have observed similar relations in their work upon the hæmolysins. The following experiments further show that the deficiency of addiment can be supplied for guinea-pigs treated against typhoid fever with immune serum

of the horse by the fresh serum of the ox, the rabbit, and the pig:—

No. of guinea-pig.	Received			Result.
	M.L.D.	Serum units.	Fresh serum.	
1	10	28	—	Died within 16 hours.
2	"	"	Rabbit's, 1 c.c.	" " "
3	"	"	" 2 c.c.	Recovered.
4	"	"	Ox's, 1 c.c.	Died in from 20 to 24 hours.
5	"	"	" 2 c.c.	Recovered.
6	"	"	Pig's, 1 c.c.	Died in from 26 to 28 hours.
7	"	"	" 2 c.c.	Recovered.

Hence freshly won serum of the three different animals examined can supply the lacking addiment for guinea-pigs. The same may probably be true of other normal sera. I therefore claim that addiment is not so special to the species as Professor Ehrlich thought.

But if the sera of these animals were kept for a few days in the ice-chest they were found to lose their power of addimentary action; that is to say, their addiment disappeared and guinea-pigs which received the same and even much larger doses of the normal sera than in the above experiments were no longer protected. Further, the addiment of the fresh-won sera was found to be destroyed by their exposure to a temperature of 53° C. during an hour. On both these grounds it follows that the addiment of the bacteriolytic action here in question is extremely labile, being destroyed by a temperature of 53° C. and disappearing naturally from separated serum with considerable rapidity. And I conclude, that the reason why immune serum which supplies immune body fails to yield addiment to the infected animal is that the latter, owing to its extreme lability, is altogether absent from stored immune serum, and not that owing to its specialism it is unavailable by a species different from that of the animal which supplies the immune serum.

3. Coming next to the question of what addiment consists we have the following facts. Anti-microbial sera have *in vitro* no bacteriolytic action—they contain immune body but addiment is absent. They may be rendered active by cellular action, as, for example, by a sojourn in the peritoneal cavity of a guinea-pig. The activity thus obtained is destroyed by heating to 56° C.—destruction of addiment. It is restored by the addition of normal serum (Bordet) or of leucocytic fluids (Hahn). Moreover, an inactive immune serum which has not been subjected to the action of the peritoneal surroundings can similarly be rendered active by the addition of leucocytic fluids (Bordet's phenomenon) and a definite relation exists between the mass of the leucocytes added and the degree of bactericidal power obtained (Bordet). Again, a bacteriolytic pleural exudate has been made entirely inactive by the removal of its leucocytes, active again on their replacement (Denys and Havet). Further, it has been shown above that addiment is present in fresh normal sera from which it disappears on heating to a temperature of 53° C., or simply by keeping, and it was also found to be obtainable in other experiments from the fresh blood-clot of the animals already mentioned. It follows that the addimentary ferment is definitely associated with the leucocytes and is not a ferment circulating freely in the blood-plasma, as Ehrlich teaches. The leucocytes possess addiment even *in vitro* and can supply it to a serum from which it was previously altogether absent; and the addiment contained in the fresh sera is merely such as is set free by the destruction and breaking up of leucocytes.

4. It has been stated by von Dungern that the addiment is not increased in quantity during immunisation. If this were so it would imply that the newly-formed leucocytes of the leucocytosis, which admittedly occurs, are deficient in their characteristic and essential ferment; and this is almost inconceivable. Moreover, if new addiment is not formed it should be found impossible to immunise an animal to withstand a larger dose of the infective agent than that number of M. L. D. at which deficiency of addiment appears in unimmunised animals—e.g., in these experiments four M. L. D. of bacillus typhosus; and this is evidently not the case. Experiments, however, have shown that long after deficiency of addiment has become evident it remains possible, by giving

a large excess of immune body (immune serum), to protect the infected animals which thus have time allowed for the formation of fresh addiment by the provision of excess of immune body which enables the new addiment produced to deal with the bacterial multiplication occurring in the interval. Thus, though deficiency of addiment was evident at five M. L. D., and the immune serum contains no addiment at all, yet it was possible by an excess of serum to protect against 10 M. L. D. The addiment, therefore, undergoes increase during immunisation.

5. The immune body is formed by leucocytes. For let that atom-group of the bacterium which is taken up by cell-receptors in the animal and thus excites the formation and splitting off of immune body be spoken of as the I-group of the bacterium. Then the corresponding receptor must be present in the leucocytes, for thus only can be explained the destruction of bacteria in the naturally immune since the plasma of such animals contains no immune body. On the injection of bacteria in immunisation these receptors will give rise under the stimulating influence of the I-groups to a formation of the immune body by their proliferation and splitting off into the plasma. But even if suitable receptors for the I-groups were present in other tissues besides the leucocytes and could similarly give rise to the formation of an anti-body to these groups of the bacteria, this would not constitute true immune body. For the latter is supplied not only with an I-group haptophore, but also with an addimentophil haptophore, while the hypothetical antibody formed in other than the leucocytic tissues having no necessary relation to the addiment could only by an extreme coincidence possess a haptophore attractive to the leucocytic ferment. This difficulty did not appear so long as we could hold with Ehrlich that the addiment was a general metabolic ferment circulating freely in the plasma and possessing a necessary relationship to metabolic cell receptors generally. But I have urged that this is not the case. And, further, there has recently been proved to exist a definite parallelism between the increase of immune body and the increase of certain forms of leucocytes during immunisation, while the experiments of Deutsch and others point definitely to the formation of the protective substances in the leucocytic tissues.

6. Agglutinins have been shown to bear a close relation to protection. What is the nature of this relation? In anti-microbic sera we have at least two functions—namely, (1) bacteriolytic and (2) antitoxic, against intracellular bacterial toxins set free by the bacteriolysis. Such antitoxic action we have found by experiment to exist in the antityphoid serum here in question. Agglutination can have no relation to this antitoxic action against intracellular toxins, for it occurs equally with living as with dead bacteria. Its relation to protection must therefore be a relation to bacteriolysis. But it is not concerned in lysogenesis, which is a function of the action of immune body to addiment alone; for agglutinins cannot actually be the immune body, as supposed by Grüber, since they are formed in the lung tissue (Deutsch and more recently Moersch also), while immune body is a product of the leucocytes. Hence it is probably in relation with the only other factor in bacteriolysis—namely, the phagocytic process, which is evidently assisted by the faculty possessed by the agglutinins of bringing the bacteria together in larger or smaller masses and at rest and by the change which they induce in the bacterial envelope. And I suggest that just as in the final and essential stage of the destruction of bacteria the chemical digestive action of the addiment of the protective cell is aided by a chemical change produced in the bacterial substance by the immune body, so in the preliminary or phagocytic stage the physical process of ingestion is aided by the physical alteration induced in the bacteria and their activity by the agglutinins.

*Conclusions.*—1. Addiment is not extremely special to the

species. 2. Addiment is a leucocytic ferment. 3. Addiment is increased during and by immunisation. 4. The immune body is produced exclusively by the leucocytes. 5. Agglutinins assist the phagocytic process.

Oxford.

## GYNÆCOLOGICAL CASES.<sup>1</sup>

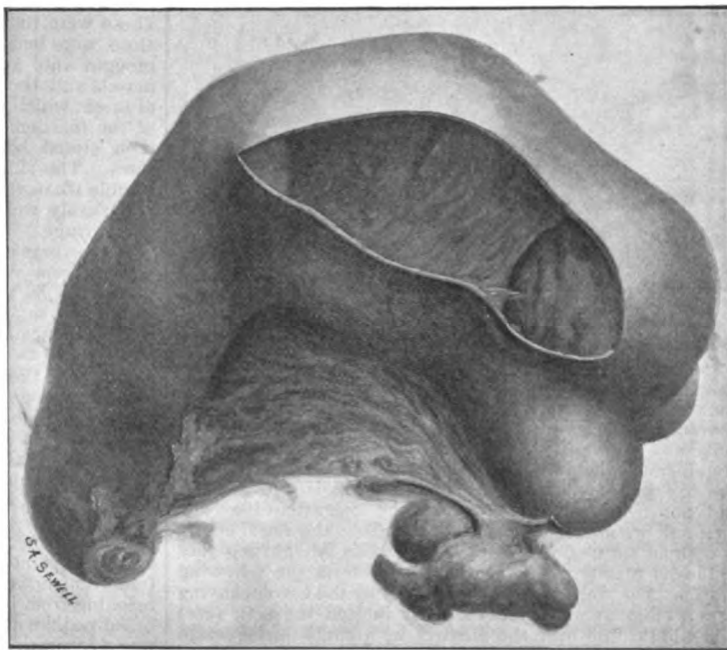

By H. MACNAUGHTON-JONES, M.D., M.Ch. R.U.I.,  
F.R.C.S. IREL.

DR. MACNAUGHTON-JONES, on exhibiting the cases, said:—

*Primary tuberculosis of the Fallopian tube with pyo-salpinx.*

—These appendages were removed from a patient, aged 22 years. She had been married for two and a half years at the time of the operation and had completed her first pregnancy at the end of the first year of her married life. She was brought to me by Dr. H. Disney in January, 1901. She then complained of considerable and constant pain in the left side, with inability to walk, and dyspareunia. The catamenia had been regular and normal. On examination I found the adnexa on the left side to be much enlarged, softened, and very sensitive. The right were not enlarged, but I could distinctly feel adhesions. I advised immediate operation, either exploration by colpotomy or abdominal celiotomy, the affected adnexa to be dealt with either by removal or resection according to circumstances. This was practically agreed to, but by the advice of a distinguished obstetric physician who saw her immediately after I did operation was declined and the hope was expressed by him that by rest and a course at Woodhall Spa none would be required. I did not see the patient again until the day before I operated on her. This was on July 10th, 1901. Pain had then been for some time agonising, and she herself demanded operation. The condition of the right adnexa can be judged from the specimen (Fig. 1).

FIG. 1.

Primary tuberculous pyo-salpinx. (Sac opened.)

The Fallopian tube was distended with pus, forming a long crescentic swelling one and a half inches in diameter at its widest part, the surface of the tube being adherent. "The right ovary, though fixed by some adhesions, was healthy. A large cavity filled with serous fluid (perimetric cystoma) had formed behind the meso-salpinx and between the

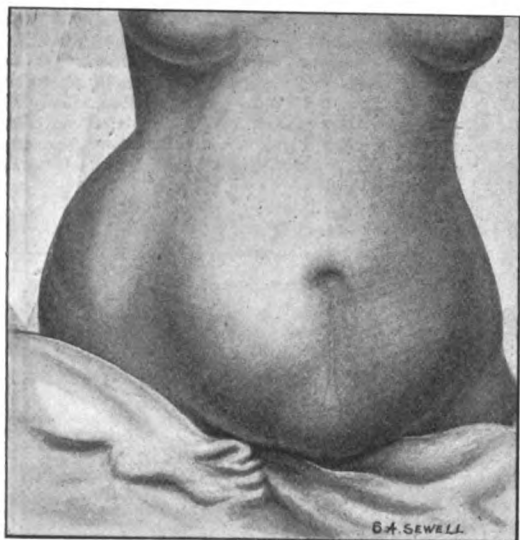

<sup>1</sup> A paper read before the British Gynæcological Society on Oct. 10th 1901.

distended tube, the ovary, and the adjacent viscera." The following is the conclusion of Mr. J. H. Targett's report on the specimen: "The external surface of the specimen is covered with thin fibrous adhesions in which many miliary tubercles are embedded. The lumen of the tube is filled with thick caseous pus and the inner surface is shaggy from ulceration of the mucous membrane. There is very little thickening of the wall of the tube anywhere and in some parts it is much thinned by distension and ulceration. Microscopical sections of the undilated uterine end of the tube exhibit general thickening of the mucous membrane and infiltration with miliary tubercles. The epithelial lining is for the most part intact."

This is the second case I have had of primary tuberculosis of the Fallopian tube in a young woman otherwise in perfect health, and with no family history of tuberculous disease. The first which I have reported in full elsewhere<sup>2</sup> was complicated with hæmato-salpinx. The particulars of the last case speak for themselves. The patient made an uninterrupted recovery.

*Large hernia following on cœliotomy operations.*—This was the largest post-operative hernia I have ever seen. The drawing, which was taken from a photograph, gives a fairly good idea of its extent. When I saw the patient in May of the present year the bowel was down in a large sac which protruded over the pubes, where there was a more defined pouch, covered only by the integument (Fig. 2). A

FIG. 2.

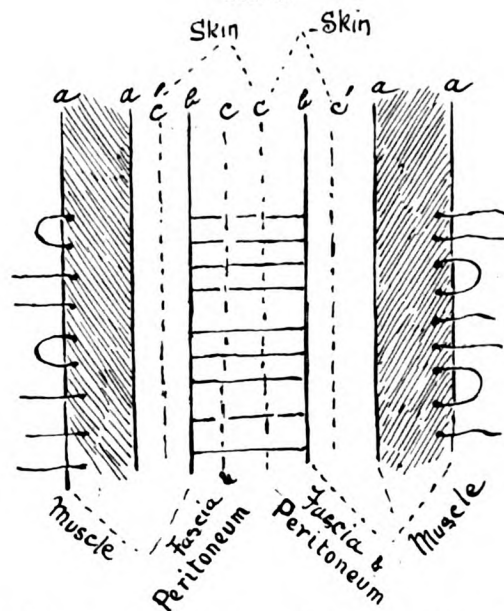

Before operation. (From photograph.)

large space of several inches separated the recti muscles and fascia. The bowel appeared to be adherent in parts to the parietal covering. The patient was subject to recurrent attacks of severe pain and had to be confined to bed for several weeks before operation. This was due to attacks of subacute peritonitis. The old cicatrix extended from a short distance below the umbilicus to about two inches above the pubes. Cœliotomy had been twice performed. I did not learn until the day of the operation that the abdominal wound had been closed after the last operation without sutures, the parts having been brought together by adhesive plaster. I determined to perform the following operation. The steps may be understood by the accompanying diagram (Fig. 3). Having carefully incised the skin (c c) in the middle line over the cicatrix by a cautious dissection vertical to the bowel, which was immediately subjacent and in parts adherent, it was reflected back to the extent of some three inches at either side (c'). Some dense fascia (b) was then exposed continuously with the peritoneum and the fascia of the rectus (a a). This fascia also was raised and reflected back, the dissection including a portion of the rectus sheaths (a a). All bleeding points from adhesions of the bowel were secured. The whole omentum and bowel were then covered with a sterilised napkin wrung out of warm formalin solution. Mattress sutures were then carried

from side to side in the following manner. Two straight ovariotomy needles, each threaded with fairly strong silver wire, were passed parallel from the outer border of the rectus including the fascia, across, and passing under the dissected fascia were brought out at corresponding points on the opposite side. Six of these were carried alternately in the manner shown in the drawing, and a single strong wire was passed at the upper and lower angles of the wound. The

FIG. 3.

central ones were separated, and the napkin was caught in the centre and readily withdrawn between the sutures. These were then tightened, and the ends, twisted and cut close, were buried in the rectus muscle at either side. This brought into apposition a line of rectal fascia with the muscle and the underlying peritoneum, leaving a raised flap of fascia which projected at either side for the entire length of the incision. This was pared and made to overlap, and then closed with silkworm-gut sutures, which were cut short. The skin margins were then united. There was no trouble whatever after the operation, which the patient bore remarkably well, and she has since left this country on a long voyage.

*Very large fibromyoma; hysterectomy; recovery.*—The patient from whom this tumour was removed was a multipara, aged 50 years. Her last pregnancy was in 1890. She had never suffered any particular pain, and could not date the commencement of the growth. She noticed an enlargement some two years since, but only within the last few months had there been a rapid increase in size. The periods had been irregular in occurrence and quantity, and there was a considerable loss a few days before operation. On examination a large moveable abdominal tumour was found, semi-solid to the touch, and associated with the uterus, the cavity of which was over five inches in length. The abdomen was enlarged much beyond the size of that of the full term of pregnancy. I operated on Sept. 12th, the patient having a full knowledge of the dangers connected with the operation. The enormous tumour was found to be free from adhesions, and was delivered through an incision reaching from below the ensiform cartilage to the pubes. A broad pedicle attached it to the left broad ligament and there was a separate attachment to the uterus. The capsule having been completely detached by a circular incision and stripped down the attachment to the uterus was secured and supra-vaginal hysterectomy completed. The large broad ligament pedicle was then ligatured in segments and the tumour was detached. After removal it was found that the bladder had been opened. The wound was closed by catgut sutures and a catheter was retained. The operation lasted altogether for two hours and during the last half-hour subcutaneous (sub-mammary) injections of artificial serum were maintained. The anæsthetic given was chloroform. There was dangerous collapse on the delivery of the tumour and

<sup>2</sup> Diseases of Women, eighth edition, p. 622.

again towards the close of the operation. As there was some bleeding from the bladder it was washed out at intervals with a solution containing 30 minims of liquid extract of suprarenal capsule. The tumour proved to be a solid fibromyoma and it weighed 28½ pounds. Its size and shape can be estimated from the accompanying illustrations taken from photographs (Figs. 4 and 5). The table on

FIG. 4.

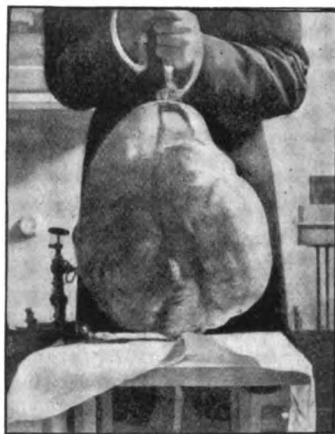

FIG. 5.

which the tumour rests measures 16 by 16 inches. (The uterus and adnexa are not shown.) So far, with the exception of some cystitis and pus in the urine, the patient has made an excellent recovery.

Harley-street, W.

### THE PREVENTION OF ASPHYXIA WHEN THE BIRTH OF THE AFTER-COMING HEAD IS DELAYED:

A HISTORICAL NOTE.

By G. F. BLACKER, M.D. LOND., F.R.C.S. ENG.,

OBSTETRIC PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE  
GREAT NORTHERN CENTRAL HOSPITAL.

THE danger of asphyxia to the child in cases of breech presentation where the birth of the head is delayed is always great, and with a view to obviating the risk numerous means have been devised of delivering the after-coming head with the maximum of rapidity and the minimum of danger to both mother and child. In many instances, however, even under the most skilful treatment the child is born asphyxiated and life cannot be restored, and the management of such a case is always a matter of grave anxiety to the medical practitioner. By a curious coincidence in THE LANCET of

Sept. 21st Dr. Edwin Smith writes (p. 815) advocating the use of a catheter passed into the child's mouth in those cases where there is danger of asphyxia, and in the same issue of THE LANCET Mr. G. W. Ord describes (p. 790) how 12 years ago he saved the life of an infant when the head was delayed in the vagina by passing a silver male catheter into the mouth and so enabling air to enter the lungs. Dr. Smith takes the precaution—a wise one at the present day—of apologising in advance to the gentleman who may write to say that he described the device many years ago. I am afraid, however, that this particular practitioner is far beyond the power of writing letters to the medical journals. The originator of this method of avoiding asphyxia to the child in cases of breech presentation would appear to have been Benjamin Pugh of Chelmsford who, in his Treatise on Midwifery published in 1754, p. 49, in discussing the treatment of such presentations, writes:—

When the Parts are well made, and the Child in proportion, happy the Case! it will come then any Way, the Arm being brought down, the Head only remains to be extracted, which must be done with as much Expedition as possible, as indeed the Arms ought to be; for consider when the Child has passed the Navel, the Circulation between it and the Mother is stopp'd from the Pressure of the umbilical Rope; you must then introduce the Fingers of your Left-hand into the Vagina under the Child's Breast, and put the first and second Fingers into the Child's Mouth pretty far, so far, however, that you are able to press down the Child's Tongue in such a Manner that by keeping your Hand hollow, and pressing it upon the Mother's Rectum the Air may have access to the Larynx, you will soon perceive the Thorax expand as the Air gets into the Lungs. Many Authors make very little Trouble in extracting the Head, but without a well formed Pelvis every Operator must know there is Difficulty, and great Danger of losing the Child by its Stay in the Passage; but by this Method of giving the Child Air, I have saved great Numbers of Children's Lives which otherwise must have died. And now you may rest yourself a little, which you have great Need of sometimes. If the Child does not breathe immediately upon Delivery, which sometimes it will not, especially if it has taken Air in the Womb; wipe its Mouth, and press your Mouth to the Child's, at the same time pinching the Nose with your Thumb and Finger to prevent the Air escaping; inflate the Lungs rubbing it before the Fire; by which Method I have saved many. Before I made use of this Method and pressing externally, to assist in Extracting the Head, I found many Children were lost in this Situation, for want of Air, which put me upon both Inventions, as likewise a third, which was a curve flattish Pipe, as likewise a flexible one, that I introduced into the Child's Mouth, as near to the Larynx as I could the other End external, which I found answer; but now as I find my Fingers will generally answer I seldom make use of it.

In the plates appended to this work is figured the tube (Fig. 1) which Pugh was in the habit of using. It is described as follows:—

The Air-Pipe as big as a Swan's Quill in the Inside, ten Inches long, is made of a small common Wire, turned very close (in the Manner Wire Springs are made) will turn any Way; and covered with thin soft Leather, one End is introduced up the Palm of the Hand, and between the Fingers that are in the Child's Mouth, as far as the Larynx, the other End External.

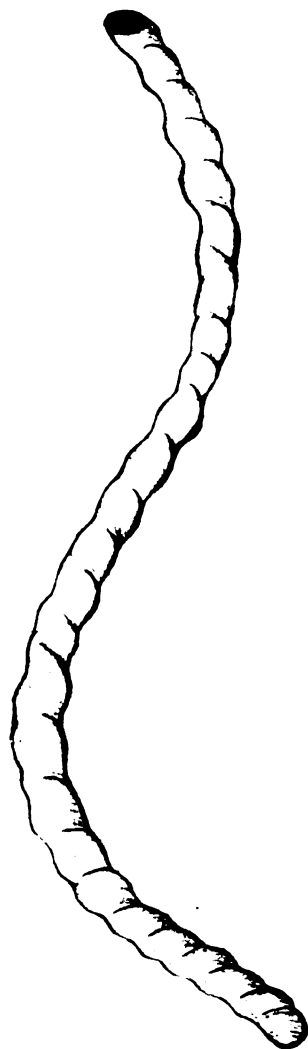

The next reference of importance to be found relating to this ingenious method is in a little book entitled "Essai sur les Accouchemens contre Nature ou Méthode Assurée de Délivrer les Femmes, par Pierre-Etienne Morlanne," published at Metz in the year 1802. In describing the method of making jaw traction in breech presentations the author says: "After having seized the chin the surgeon places one or two fingers in the mouth of the child, depresses the tongue, and facilitates by this procedure the introduction of air into the chest. This operation with which a frequent use in preternatural confinements has rendered me familiar, should take its place as a fundamental principle of the art which aims at preserving the life of the child. I have seen in labour rendered difficult by the size of the head or the smallness of the pelvis—I have seen, I say, the child live for more than half an hour by the admission of air into the bronchi, and ultimately survive the difficulties of its extraction when one has employed the proper means to revive it."

In 1829 Dr. Jacob Bigelow, at that time professor of materia medica at the University of Harvard, published a paper in the *American Journal of the Medical Sciences*<sup>1</sup> on the Means of Affording Respiration to Children in Reversed Presentation. He draws attention to the fact that not uncommonly while the practitioner is making efforts to extract the after-coming head there occurs a convulsive jerk or spring of the child which indicates that a state of extreme danger exists and that the time has come at which the child must breathe or will speedily die. He recommends that when the head is low down the accoucheur "should introduce the hand to which the face of the child looks till the middle fingers rest upon the mouth of the child."

<sup>1</sup> Vol. iv., p. 285.

The hand is then to be raised from the throat of the child, making the ends of the fingers a fulcrum and pushing the perineum backwards. The air will thus pass upwards as far as the chin of the child. The middle fingers are now to be separated about half an inch from one another, and thus a complete passage will be formed between them by which the air will reach the mouth of the child. If the child be in a healthy state it will immediately breathe and cry and the delivery of the head may be safely postponed until the natural pains recur. If from any degree of asphyxia the child does not immediately breathe it may often be made to do so by dashing cold water upon the body or by other stimulating processes. When the head is so

FIG. 1.

Pugh's tube, from the original engraving.

high in the pelvis as to be reached with difficulty a flat tube will be found useful, made of metal, of spiral wire covered with leather, or of elastic gum, and having its largest diameter about half an inch. Such a tube may be considered as a prolongation of the trachea, and is fully sufficient to sustain life by respiration for a considerable time." He considers Pugh's advice to depress the tongue as superfluous, since it is sufficient to make a passage for the air as far as the child's lips only. Five cases are recorded in which by the use of one or other of these methods the child was enabled to breathe with its head still in the vagina. In each of the cases the life of the child was saved, while in two of them the infant cried quite plainly before the delivery of the head was completed. Professor Bigelow

FIG. 2.

Joos's tube, from the original engraving.

was acquainted with Pugh's book, and he quotes his practice. As he points out, however, after 1754 this method seems to have been lost sight of, and no mention of it is to be found in the works of Smellie, Denman, Hamilton, and Burn, nor have I been able to find any allusion to it in Levret, Johnson, Rigby, Ryan, Blundell, Ramsbotham, or Meadows. In most of the text-books published about the middle of the last century after the publication of Bigelow's paper the practice is alluded to, as, for instance, in the treatises of Meigs, Tyler Smith, and Churchill.

Simpson in his paper on Turning as a Substitute for Craniotomy presented to his pupils in 1850, in discussing the mortality to the children and the means by which the effects of compression of the cord may be averted, alludes to the works of Pugh and Morlanne, and quotes two cases (Case 60, p. 135, and Case 62, p. 136) recorded by Dr. Lee in his "Clinical Midwifery" (second edition, published in 1848) in which by forcible retraction of the perineum the child was enabled to breathe in one case for 20 minutes and in the other case for nearly half an hour after the pulsation in the cords had entirely ceased. In both instances the children were born alive and they survived, and in one the perineum was uninjured.

Barnes, in his Lectures on Obstetric Operations,<sup>2</sup> states that he has kept a child alive for 10 minutes in a case of breech presentation by holding back the perineum and so enabling air to enter the chest.

In the *London Medical Gazette* of Oct. 22nd, 1847, p. 720, Dr. Joos of Schaffhausen described a very ingenious instrument by which he proposed to prevent compression of the cord and so avoid the danger of asphyxia in pelvic and other presentations. This device (Fig. 2) consists of a tube from four to eight inches in length and of a diameter sufficient to contain the umbilical cord. It has a slit equal to one-twelfth of its circumference along one side. The tube is made of caoutchouc or leather, with a series of steel rings three lines broad inserted into it at a distance of one line apart. By the insertion of a finger into the slit the tube is opened up to admit the cord into its interior, and as the steel rings are sufficiently strong to prevent its compression, by placing the tube, or if necessary two such tubes, inclosing the cord between the child's head and the pelvis all danger of interference with the placental circulation by pressure is avoided. "The application of the instrument," says Dr. Joos, "may take place during the act of birth by presentation of the breech or feet and in cases in which a fatal pressure upon the cord is to be feared." The use of such a tube or tubes would be practically impossible in the majority of cases and there is no evidence forthcoming that even its inventor ever put it to the test of actual employment.

Hardly any of the writers of modern text-books on obstetric medicine refer to Pugh's method of overcoming the danger from asphyxia when the birth of the after-coming head is delayed, and in this omission they no doubt exercise a wise discretion. The passage of a catheter or special tube into the child's mouth when the head is lying high up in the pelvic cavity is only likely to lead to a waste of valuable time, while if the head is sufficiently low down in the pelvis to admit of air reaching the mouth if the perineum be retracted its immediate extraction should be a matter of little difficulty. It is instructive to note that in three of Dr. Bigelow's cases the head was born spontaneously, while in one of them it was easily extracted by the use of forceps after an attempt to set up respiration by passing a tube into the child's mouth had failed.

The instances recorded by various observers show that in cases of extreme emergency it is possible to keep a child alive by the use of one or other of the methods described for a considerable length of time. At the present day, however, when our means of delivering the after-coming head either by combined shoulder and jaw traction, or, better still, by the application of forceps, are so certain it becomes a question whether it is not better practice to extract the head at once even at the risk of a bad tear of the perineum rather than to attempt to initiate the act of respiration while the head is still within the vagina. The warning of Barnes should not be forgotten. Speaking of Pugh's device he says: "I must warn you not to trust to these or similar plans, lest the golden opportunity be irretrievably lost. The real problem is to get the head out of the pelvis," and to this advice one may safely add the qualification, *as rapidly as possible*.

<sup>2</sup> Third edition, 1876, p. 211.

THE TREATMENT OF HEMIPLEGIA.<sup>1</sup>

By LEONARD G. GUTHRIE, M.A., M.D. OXON.,  
F.R.C.P. LOND.,

PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S  
PARK; SENIOR PHYSICIAN TO THE PADDINGTON-GREEN  
CHILDREN'S HOSPITAL.

I HAVE chosen for the subject of this paper the treatment of hemiplegia because in my experience many patients suffering from this disease are not treated at all. Doubtless they receive plenty of iodide of potassium, strychnine, and other drugs, their natural wants are attended to, they are put in and out of bed, cleaned, clothed, and fed like babies, and on bright days they may be taken out in bath-chairs or they may be allowed to sit in the sun like Old Caspar "when his work was done"; but so far as their paralysis is concerned they are too often left to themselves. The blame for this neglect rests partly on the public. Paralysis to the public means incurability; a rooted conviction prevails that a person who has had one stroke of paralysis is bound to have another, and yet a third which will be infallibly fatal. Medical attendance is therefore discouraged as useless and the medical attendant soon receives a more or less polite intimation that his visits need not be continued and that he will be "sent for if wanted"—that is to say, should the patient have another stroke and appear at death's door. Neglect of hemiplegic patients may also be attributed to the pessimistic and cynical teaching that those who get well do so without treatment and those who do not get well derive no benefit from treatment. Neither statement is strictly true. Mild cases may never recover unless treated, and severe cases, unless treated, may go from bad to worse.

Before discussing methods of treatment it is necessary to describe the conditions with which we may have to deal and which we hope to combat.

In a severe case of hemiplegia of from six months' to twelve months' duration or longer the patient's arm and leg may be quite useless and immobile. He is unable to stand or walk. His joints are fixed and any attempt to move them causes extreme pain; his shoulder is usually adducted to his side, his elbow and wrist are flexed, his forearm is pronated, and his fingers and thumb are doubled into the palm of his hand. His hip and knee may also be flexed, his thigh adducted, his knee and foot inverted, and his heel drawn up. The muscles are all wasted and some are shortened and contracted, thus causing the characteristic pose of the limbs, which cannot be overcome, and his reflexes are exaggerated. This is the extreme and incurable state of helplessness at which the sufferer from hemiplegia may arrive. The immobility of the limbs is due (1) to articular adhesions; (2) to motor paralysis leading to muscular atrophy; and (3) to spasticity or spasmodic contraction of muscles leading to permanent shortening of the stronger ones. These conditions in an advanced stage are incurable, but I submit that systematic and intelligent treatment from the first would lessen the number of incurable patients and would alleviate the lot of those not cured.

The methods of treatment at our disposal are—(1) passive movements; (2) massage and electricity; (3) re-education of movements by passive and active exercises combined; and (4) mechano-therapeutics.

*Articular adhesions* frequently cause limitations of movements. They may occur in the elbow, the wrist, the hip, the knee, and the ankle-joints, but are most common and are formed earliest in the shoulder, rendering movements of the joint painful if not impossible. A limb which might have recovered is often useless owing to their presence. Some regard adhesions as trophic, others as rheumatic, in origin. In advanced cases changes indistinguishable from those of rheumatoid arthritis may be induced, especially in patients who already have signs of that disease. The nerves in the neighbourhood of the joints may be involved and may give rise to the painful symptoms of peripheral neuritis. Whatever be their cause, in most cases adhesions are preventable. Unfortunately, it happens too often that in early days of hemiplegia a dread is entertained lest any disturbance of the patient should cause further hæmorrhage or other mischief in the brain. So

he is left to cuddle and caress his paralysed arm to his heart's content. He usually hugs it to his side and flexes his elbow and forearm across his chest in the very position which it is desirable to avoid. This fear of moving the limbs is quite unfounded. Gentle passive movements of each joint should be practised many times a day from the very first; for adhesions begin to form very early in the first week or two, during which it is advisable to confine the patient to bed. When formed they are difficult to disperse, hence the importance of preventing their occurrence or dealing with them early. Neglected adhesions soon become permanent.

*Spasticity or early rigidity* is noticed on manipulation of the affected limbs or by the patient's voluntary movements of other parts. Any lesion affecting the cerebral motor tract may give rise to it. Some attribute it to "unantagonised cerebellar influence," others to irritation of the fibres of the tract by the lesion. In late stages it is doubtless due to descending sclerosis of the antero-lateral columns. The muscles chiefly and usually affected are the adductors of the shoulder, the flexors of the elbow, the pronators of the forearm, the flexors of the fingers and the thumb, and the adductors and the opponens muscles of the thumb. In the lower extremity the adductors (rarely the flexors) of the hip, the hamstrings, the plantar flexors, and invertors of the foot are specially involved. Spasticity or early rigidity leads to structural shortening of the muscles chiefly affected, and renders the characteristic pose of the limbs permanent. This condition of late rigidity is practically incurable. The early treatment of this condition is as important as is that for the prevention of articular adhesions. Almost from the first the limbs tend to assume the attitude which may afterwards become permanent. Therefore, even whilst the patient is confined to bed all faulty positions and any tendency to adopt a particular position should be corrected. Adduction of the shoulder may be prevented by placing a sandbag in the axilla. The elbow should be kept extended rather than flexed; the tendency to flexion is easily overcome in early stages. Advantage may be taken of the curious consolation which the patient derives from playing with his paralysed arm by instructing him to alter its position himself from time to time with his sound hand. Faulty positions of the lower extremity should be similarly treated. The limb should be rotated outwards and abducted and the foot dorsiflexed and everted in order to obviate the tendency to assume opposite positions. Spasm of the hip flexors is rare, but when it occurs it may be counteracted by placing a pillow beneath the buttocks. Contraction of the hamstrings should be treated by raising the heel. Sandbags may be used to ensure favourable position of the limbs. When the patient leaves his bed similar precautions should be taken against malposition. He should never be allowed to carry his arm in a sling, but he should keep it dependent as far as possible, only flexing it from time to time should oedema appear. He should not be allowed to sit with his knees and toes turned in, but should be told to correct these positions himself with his sound hand. The principles of treatment so far aim at prevention of fixation of joints and faulty positions of limbs.

*Muscular atrophy* usually occurs sooner or later in hemiplegic limbs. It is doubtless due to disuse, but it must be remembered that not only muscular but nervous tissues suffer from disuse. Mott<sup>2</sup> and others have shown that the neurons are dependent on stimuli from the periphery for their function and nutrition. Such stimuli are derived from normal movements and alterations in tension of the skin, the muscles, the tendons, the ligaments, &c. Now, the lower motor neurons commencing in the anterior cornual cells are not directly affected by a lesion in the cerebral motor tract, but they may be indirectly or functionally affected by the absence of normal stimuli. Muscular atrophy and paralysis are the prominent features of disease of the anterior cornual cells. Probably, therefore, even when a cerebral lesion has healed recovery from hemiplegia may not take place owing to a functional affection of the lower motor neurons produced by disuse of the limbs. Hence, if normal stimuli are absent, artificial stimuli must take their place. Passive movements, massage, and electricity are such artificial stimuli. By them we may hope to preserve the nutrition of muscles and neurons alike. If we can do so it is obvious that the patient will be better able than otherwise to make

<sup>1</sup> A paper read before the Plaistow and Canning Town Medical Society on Oct. 4th, 1901.

<sup>2</sup> Croonian Lectures on Degeneration of the Neuron, THE LANCET, June 23rd (p. 1779), and 30th (p. 1849), and July 7th (p. 1) and 14th (p. 80), 1900.

use of the gradual return of power expected in most cases of hemiplegia.

*Passive movements* aid as stimuli, as well as in the prevention of articular adhesions.

*Massage*.—Massage arrests atrophy, promotes muscular growth, prevents oedema, improves the circulation of blood and lymph, renders the joint supple, and probably has a direct action on nerves and nerve centres; but massage, unless employed with gentleness and intelligence, does more harm than good. It is useless to leave a masseur who has learnt the mysteries of *effleurage*, *pétrissage*, and *hachage* in six easy lessons to work his will on the patient. The crude methods of the ordinary shampooer are not applicable to the sufferer from hemiplegia. The man who flays and mauls and thumps his patients, who wrenches instead of coaxing his stiff joints, who tortures him by rubbing the short hairs on his limbs the wrong way, and who digs his horny thumbs below the sufferer's ribs and then remarks complacently, "That's your liver," and does it again in spite of protest, is out of place in the sick-room. Having secured the services of a masseur warranted not to madden the patient by his manipulations we have yet to teach him what to do. It has already been mentioned that spasticity tends to affect certain muscles more than others and that those most affected become contracted and overcome their weaker opponents. Therefore the latter must be strengthened in order that they may hold their own. The simple rule is to massage only the weaker muscles, and their weakness is estimated by the amount of contraction commencing or present in their opponents. The adductors of the shoulder, the flexors of the elbow, the pronators of the forearm, the flexors of the fingers and thumb, and the adductor and opponens muscles of the thumb, are usually, though not invariably, contracted, and should therefore be left alone. The method of massage for improving the tone of individual muscles is *pétrissage*, or "kneading"; *effleurage*, or "stroking," promotes general circulation in the limbs. Kounindjy\* recommends centrifugal rather than centripetal massage but gives no reason, nor do I know any, for departing from the usual method. Electricity, whether faradism or galvanism, is a useful adjunct to massage but cannot take its place. If faradism and galvanism have been discredited in the treatment of hemiplegia I believe it is because so-called "medical electricians" are sometimes over-anxious to give the patient his money's worth. The currents which they employ are often far too strong, their negative electrodes are too small, and they alarm and hurt the patient by sudden makes and breaks. Any current which causes pain or produces muscular contraction is too powerful and may do harm.

*Re-education of movements*.—So far we have considered the physical causes which impede recovery and the methods of averting adhesions, late rigidity, and muscular atrophy. It must be admitted that in severe cases treatment at best is only palliative. Complete recovery cannot be expected when a part of the cerebral motor tract is absolutely destroyed. Yet we can never tell until time has elapsed the amount of destruction which has occurred. The symptoms of an organic lesion are always widely in excess of its extent. So the prospects may not be so hopeless as they appear. Even in the worst cases a certain amount of improvement may be expected, and its degree will depend on the extent of the damage. We can usually estimate this in a few months' time by the amount of spasticity and atrophy which prevails. Generally speaking, the less the spasticity and wasting the better the prognosis. Motor paralysis is of less grave significance than spasticity.

Occasionally one meets with cases in which, although adhesions, spasticity, and atrophy are slight or even absent, no improvement is manifested. After many months, or even years, the patient remains as helpless as at first. The reason may be that the patient is unaware that any restoration has taken place. He does not try to use the powers which he has unconsciously regained. He is too depressed and disheartened, too apathetic and resigned to his misfortune, or too timid to attempt to help himself. Apart from such mental conditions, which of course need appropriate treatment, he seems literally to have forgotten how to execute voluntary movements. In re-educating him we are helped by knowledge of the natural order in which recovery occurs. Thus, the leg usually recovers before the arm, the hip and knee before the

ankle, the shoulder before the elbow, the elbow before the wrist, whilst the extensors of the fingers, and especially the abductors and extensors of the thumb, are the last to be restored. The rule is that the parts whose movements are most specialised and least associated with movements of the opposite limb are the last to regain power. This knowledge is most valuable, for if we can foretell to the patient that power will return in due order in each limb or joint, and he finds the prophecy true in one instance, he will gain confidence in its truth as regards the rest and will persevere in his attempts to anticipate progress. He is less apt to mourn over his useless fingers if able to rejoice over a serviceable leg. Therefore we endeavour to fix his attention on the parts which should be recovering rather than on those which are still obviously paralytic. He has to be content to sit up before he can stand, to stand before he can walk, and to move his shoulder before his elbow, his wrist, and his digits; but he will often be unable to regain any of those powers unless literally taught to do so. The method of teaching is to foresee the dawning approach of power and to elicit it by means of passive movements. It is useless merely to tell such a patient to elevate his arm at the shoulder. He will only sigh, "I cannot." But tell him to do so and at the same time do it for him, and he will gradually learn to raise it himself. At each attempt the operator does less and the patient does more. So the essence of re-education is in the use of passive and active movements combined.

This principle may be applied in the re-education and amplification of all movements. For instance, a patient has learnt to walk but complains that "one foot is always walking into the other and tripping him up." On examination we find that he always sits with his knees and toes turned in. He is unaware of the necessity of practising abduction, rotation outwards, and eversion of the limb, and he is quite unable to execute these movements until taught by passively working the thigh and the foot and encouraging him to make voluntary efforts to do so at the same time. Similarly, although he knows how greatly foot-drop interferes with his walking, he will not try to dorsiflex his foot unless persuaded. He must be taught to make the effort whilst sitting, helping himself meanwhile by putting on a strap attached to the fore part of his foot. Or, again, he has never learned to use his hip flexors. He circumducts his leg or drags it behind him and has difficulty in getting upstairs. We may teach him to flex his hip on the same principles. When some power has been regained it may be improved by making him stand holding the back of a chair and then directing him to place his affected foot on the rungs from the lowest upwards. Kounindjy uses miniature staircases for this purpose.

*Mechano-therapeutics*, such as weights and pulleys, elastic traction apparatus, &c., are only of use to increase powers already partially regained. The strength of muscles overcome beforehand by contraction of their opponents cannot be improved by increasing their labour.

*Disordered association*.—The normal *alternate* association of leg movements in walking is often impaired and perverted after hemiplegia. The patient may appear to try to move both legs forward at once. Directly he advances the sound limb the affected one becomes rigid and is dragged painfully behind. To lessen the difficulty he should be taught to advance the unsound leg before the sound, bringing the latter up to the level of the former after each step. He needs to be lightly supported on the paralysed side by an attendant, otherwise he will not rest on the affected leg for fear of falling. It is desirable to prevent a fall, of course, but the support which is given should be moral rather than physical. For this reason the help of an attendant is preferable to that of a stick or crutch. The patient, if able to use either implement, is apt to make it a substitute for his weakened leg instead of an adjuvant.

*Ataxy*.—Want of precision in movements often follows recovery of both limbs. Exercises on the Frenkel system for the treatment of locomotor ataxy are useful in such cases. Games such as draughts, halma, or solitaires may be recommended, or targets may be constructed on which the patients practise touching the bull's-eye and various circles with the forefinger. In all these exercises the patient "must not hesitate or he is lost." For ataxy of the lower extremity Frenkel's various apparatus may be used whilst the patient is lying in bed. He should also stand supported by the back of a chair and then, resting on his sound leg, place the foot of his weak one into wooden curtain-rings or chalk marks placed in various positions on the floor, touching each in

\* Archives de Neurologie, vol. x., No. 59.

turn as directed. The pain of neuritis may be relieved by smearing the limbs with equal parts of camphor and chloral hydrate, or glycerine and belladonna, and sometimes mild galvanism is of service.

#### SUMMARY.

1. Neglect and want of treatment aggravate severe, and retard the recovery of mild, cases.
2. The evils to be foreseen and guarded against are articular adhesions, late rigidity, and muscular atrophy.
3. Articular adhesions should be prevented by passive movements of each joint from the very first.
4. Faulty positions of the limbs should be constantly corrected or they will become chronic.
5. Contraction of muscles should be treated by endeavours to improve the nutrition of their weaker opponents.
6. Massage, passive movements, and to a less extent electricity, should be used with this object. These agents not only counteract muscular atrophy from disuse, but probably take the place of normal stimuli and invigorate the neurons.
7. The recovery of mild cases may be often hastened by re-education of movements. Want of re-education frequently prevents recovery.
8. Re-education consists in a combination of passive and active exercises.
9. Movements should be first encouraged in those parts which naturally tend to recover first.
10. Incoördination and general weakness of limbs which have yet regained power of movement should be treated by exercises and mechanical therapeutics.
11. It is important to find out what the patient can do and to make him do it.

In conclusion, this paper deals with the treatment of hemiplegia as a condition without reference to its cause, for whether the cause be hæmorrhage or occlusion of cerebral vessels by embolism or thrombosis is immaterial. The principles of treatment will be the same and need not interfere with other measures taken for the relief of the disease which gave rise to the hemiplegia.

Upper Berkeley-street, W.

## THE TREATMENT OF SYPHILIS, WITH SPECIAL REFERENCE TO THE BEST METHODS OF ADMINISTERING MERCURY.

By WINFIELD AYRES, M.D.,

GENITO-URINARY SURGEON, BELLEVUE HOSPITAL, O.D.P., NEW YORK;  
INSTRUCTOR IN GENITO-URINARY DISEASES IN NEW YORK UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE;  
INSTRUCTOR IN GENITO-URINARY DISEASES IN THE NEW YORK POST-GRADUATE HOSPITAL, ETC.

THE use of mercury in the treatment of syphilis was begun over 400 years ago. For a time the inunctions and fumigations were used so thoroughly that the patient suffered more from the drug than from the disease, and, as a consequence, the school of anti-mercurialists was established. Later, as the uses and evils of mercury were better understood, more and more were converted to a belief in its efficacy until at the present day there are few physicians who do not use mercury in some form. The disease is so insidious and takes so long to eradicate that whatever preparation is selected to deal with it it must be one that is easily borne and will not cause any general disturbance. The method of treatment has long been, and still is, a subject of discussion, the majority claiming that the interrupted method is preferable, while the minority contend that the drug should be given constantly for a period of about three years. As a rule, those who advise the interrupted treatment give the medicine for life, thereby admitting that the disease is incurable. Those, on the other hand, who advocate the constant treatment assert their belief that the disease can be eradicated if the medicine is systematically taken for the prescribed period—namely, three years. It seems to me that this much, at all events, is certain—that there is no hope of eradicating the disease unless the full dose is given constantly for something like the period indicated. In practice the rule should be, first find the point of tolerance and then hold the

dosage just below that point. Now arises the question, How soon shall treatment begin? The answer to that question is, Just so soon as the diagnosis of syphilis can be made, whether eruption has appeared or not. The initial lesion of syphilis assumes one of three forms. It is either an ulcerated sclerotic nodule, an eroded sclerotic nodule, or a dry nodule. The diagnosis of chancre can be made safely on the two latter forms, but no man is capable of making a positive diagnosis of chancre on an ulcerative lesion, and in such cases it is better to wait for the secondaries to appear or until the lesion assumes the characteristics of either the dry or the eroded nodule. The next point to be considered is, Does enucleation of the chancre have any effect on the course of the disease? There have been cases reported where no eruption followed enucleation, but it seems to me that in such cases the diagnosis should be questioned. In the majority of cases undoubtedly the eruption follows just as if no enucleation had taken place, and therefore it would seem there is no ground for supposing that enucleation has the effect of aborting the disease.

Some authors urge as an objection to early treatment that if mercury be given before the secondaries appear one can never be certain of the case being syphilis, because the mercury either prevents the eruption from appearing or masks it so that diagnosis cannot be made. If, however, the above rule is followed in regard to the giving of medicine during the chancre stage no question of diagnosis can arise. The advantage of giving mercury during this primary stage is that it either prevents or materially diminishes the eruption, and as a consequence the patient is not disfigured either temporarily or for life, as otherwise he is in danger of being. The effect of the early administration of mercury, in other words, is always to modify the secondaries—that is, they are neither so severe nor so determined; and there is this further advantage that when they do appear the point of tolerance has been established and no time need be lost in determining the dosage.

In passing it may be observed that ulcerating lesions should be treated only locally. If the ulceration is considerable it should be cauterised by some agent that does not destroy the tissue deeply. Saturated solution of potassium permanganate has been of most service in my hands, while a 20 per cent. silver nitrate solution has also been found very efficacious, especially in shallow ulcers. Nitric acid should never be used on an ulcer which is under suspicion, as it will cause too deep a slough and resulting scar. About the best dressing to apply is a piece of cotton soaked in balsam of Peru.

Before leaving the question of diagnosis I may refer briefly to the Justin test, with which I have made very thorough experiments. My experience has been that in all cases of unquestionable syphilis this test responds beautifully, while in all cases of doubtful syphilis the results are invariably negative. Several of the latter cases have proved to be syphilis later. I had 19 cases of chancre tested by this method. All were followed by eruptions, no medicine being given in any of the cases until the eruption appeared. In five out of these cases the test showed a decrease of hæmoglobin, while there was no decrease in the remaining 14. Therefore, I am forced to the conclusion that even in the testing of chancres this method is not of very great service. Later tests are those made by the use of the microscope, the theory being that the existence of syphilis is shown by the presence of three or more crenated blood corpuscles in a particular fluid and by the fact that the blood corpuscles generally do not have a tendency to form rouleaux. This condition, however, occurs in many other cases of secondary anæmia, and therefore this test is of little value except to the expert microscopist.

If a positive diagnosis cannot be made from the appearance of the chancre the patient should be put in first-class condition by means of tonics and the regulation of his diet and habits, special attention being paid to the condition of his digestive organs. And here I may say parenthetically that even when it has been established that a patient has syphilis it is my custom to allow him the moderate use of stimulants if he has been accustomed to them, and this I continue to do all through the treatment of the disease. Tobacco should be barred so long as there are any eruptions in the mouth, but when the eruptions have disappeared the use of tobacco should be allowed, as the irritation it produces will cause the eruptions to reappear if the patient is not getting sufficient mercury, while no harm will result in the event of the dosage being adequate for the control of the disease. Generally

speaking, it is much better for a patient to remain about his business, provided he takes his medicine regularly, than it is for him to be shipped off to any of the springs. The exceptions to this rule are to be found in cases where the disease is so severe as to call for more radical treatment than can be given at home.

This brings us to the question of general treatment. There is practical agreement among the authorities that just as soon as the diagnosis of syphilis can be made the patient should be given some form of mercury, but there is wide diversity of opinion as to which form is best for the purpose, and each surgeon usually selects that from which he has obtained the most favourable results in his individual experience. Only in regard to one other point, besides the necessity of having recourse to the medicine, is there anything approaching a consensus of view, and that is that in order to exercise its anti-syphilitic influence the mercury must circulate in the blood in minutely divided particles, and the assumption is that when chemical combinations of mercury are administered they are broken up in the system into such particles and then absorbed into the circulation.

Of the drugs that are frequently used in the treatment of syphilis I regard blue ointment as of most value. After it I would place mercuriol, bichloride, protoiodide, tannate, blue mass, grey powder, biniodide, fumigations, inhalations, and for extreme cases hypodermic injections of mercury. The unguentum hydrargyri comes to us in the form of metallic mercury minutely subdivided, and it is absorbed directly into the blood in the way described. I do not think that the theory that the mercury is inhaled from inunction is well founded. An additional advantage possessed by blue ointment is that, not being given by the stomach, it does not cause any gastric or intestinal trouble. There is, however, a serious objection to this form of administering mercury, and it is this, that it is extremely nasty, and therefore very few patients can be induced to continue it for any length of time. The method of giving the inunction is as follows. The patient may lie on a table, or sit on a chair, leaning on the back. The rubbing should by preference be done by an attendant who ought to have on a pair of rubber gloves to protect himself. The sites selected for the rubbing should be the back and loins. When it is impossible for the patient to have a rubber he can apply the inunctions himself, taking care to select those parts of the body where the lymphatics are most freely distributed—namely, the inner sides of the arms, the axillary line of the chest, the inner sides of the thighs, and over the popliteal spaces. This gives eight areas that can be used for the inunction, and they should be used in rotation. If the patient has an attendant the dose in a northern climate should be about one drachm or even one and a half drachms. If the patient does the rubbing himself he should use from one and a half to two drachms, as no patient will rub the mercury in so thoroughly as an attendant. After the inunction the patient should put on his shirt or drawers and wear them through the night. In the morning he can take a hot bath and wash off the mercury. The amount of inunction should be governed by the patient, some being able to take much more than others, the same as internal medications. Whenever the teeth become the least bit sensitive the inunction must be stopped for two days and then resumed at a smaller dose and kept at the point just below tolerance.

In regard, next, to protoiodide, probably this medicine is used at the present day more than any other in the treatment of secondary syphilis. In some cases it controls the symptoms remarkably well, but in the majority of cases it is of very little use. Valuable time is often lost by starting a patient on this preparation of mercury, it being found later that some other form of the medicine will have to be given to control the disease. The chief objection to protoiodide is that in a large number of cases it causes intestinal disturbance, and not unfrequently gastric disturbance as well, while in others it produces what can only be described as a general breakdown. Just about the time when results are expected from the drug the patient may lose flesh rapidly or gastro-enteritis may suddenly develop, and in either case his medicine will have to be stopped and some other preparation of mercury given. It is customary in using protoiodide to start with one-fourth or one-fifth of a grain three times a day and increase the dose slowly until constitutional effects are produced, as shown by slight tenderness of the gums or until signs of improvement are manifested. It is sometimes necessary to give enormous doses of this drug before any improvement is noticed.

Tannate of mercury acts in about the same way as protoiodide, and it has been my experience that those cases that do well under one drug do well also under the other, and *vice versa*. With tannate of mercury it is customary to begin with one-half grain three times a day and to gradually increase the dosage in the same way as when using protoiodide.

Blue mass, if exhibited with a slight intestinal astringent like tannic acid, will control symptoms of syphilis very satisfactorily, but if given alone it is apt to cause intestinal and gastric disturbance. The usual dose is from one to three grains three times a day.

Grey powder is sometimes borne where other preparations of mercury cause disturbance, the dose being one grain gradually increased to the point of tolerance. It is a very mild preparation of mercury and is probably the best for treating children. The objection to this preparation is that unless perfectly fresh the metallic mercury separates from the chalk and gathering into larger globules settles at the bottom.

Bichloride is a very reliable preparation of mercury. It almost invariably controls the symptoms. It has, however, to be taken in solution and it frequently causes gastric and intestinal disturbance, though not to anything like the same extent as protoiodide. This preparation should not be given in the syrup of sarsaparilla compound because it forms a precipitate. It is better given in the tincture of gentian compound, or if iron is indicated it can be given in elixir gentianæ cum ferro.

Fumigations are of great benefit in cases of obstinate skin eruption. For this method of treatment probably calomel is the best and it can be given in 20-grain doses. Fumigations may be given every second, third, or fourth day. This treatment, however, is rather exhausting to the patient.

With regard to inhalations, lately there has been recommended the wearing of cotton or woollen pads soaked with mercury on the chest, the idea being that the mercury is inhaled by the patient. It is admitted, however, even by those who strongly recommend this treatment, that it is only of service in mild cases of syphilis.

As to iron, it is not well to give this in treating syphilis until the tolerance of the patient to mercury has been established, because if iron and mercury are given together at the outset an explosive salivation is liable to occur. Yet the symptoms of some patients which it is impossible to control by mercury alone will be found to come under control when iron is added.

With regard to hypodermic injection, in hypodermic injections of mercury the bichloride is the form of the drug which is most often used. Calomel is also frequently given. Probably as handy and trustworthy a preparation as one can use is the following: bichloride of mercury, one grain; glycerine, one drachm; and water, one drachm. This is a stable preparation and can be kept for several days or weeks. 10 minims of this will represent one-twelfth of a grain of bichloride of mercury. It is always the custom to give an injection directly into the muscles of the gluteal region. The technique is as follows. First clean the skin by soap and water and then by bichloride sponge. Draw into the syringe a few minims of 4 per cent. solution of cocaine. Drive the needle directly into the gluteal region as far as it will go. Introduce about four drops of cocaine. Then unscrew the barrel of the syringe. Leave a drop of the solution in the cap of the needle, the needle, of course, being left in the tissue. Throw out all the cocaine left in the barrel of the syringe and fill it with about 15 minims of the preparation given above. Then screw the barrel of the syringe on to the needle again, being careful that no bubble of air is admitted. Throw the solution into the tissue, using in the first injection 10 minims. Two days afterwards the patient should be given another injection of the same dose. If two days later he shows no improvement the dose may be gradually increased, giving 12, 14, or 16 minims, as the case requires. After the injection the syringe is withdrawn and the thumb is placed over the puncture, but the place is not rubbed in the least. If the technique has been carefully followed an abscess will never result. It has been my experience that patients do not like this form of treatment and that while they may return for one or two injections, after that they are likely to disappear. Yet in very severe cases there is no doubt but that the hypodermic method will control the symptoms much better than any other way of exhibiting the drug. After injections nodules and painful spots are often left in the gluteal region, sometimes persisting for several

years and being very disagreeable to the patient. Still, I believe with Lydston<sup>1</sup> that if hypodermic injections can be performed without the production of local injurious effects they represent the ideal treatment for syphilis. I have used mercuriol hypodermically in two cases. In one of these no trouble followed the first injection, but after the second injection a large abscess formed on the site. As I did not give the injections myself I do not know whether the technique was followed. In the other case no abscess resulted but the injection was fully as painful as those made with bichloride; and there is this drawback to the use of mercuriol hypodermically, that it has to be prepared fresh each time it is wanted for use. The results obtained by using mercuriol hypodermically as far as controlling the symptoms is concerned are very good. I have also used cypridol in two cases. Following the directions of the manufacturer I gave ten minims every second day in the gluteal region. There was no pain, but the disease was not controlled and excessive salivation followed, necessitating a change of medicine. Possibly further experiments with this drug may show better results.

I now come to the second part of my paper in which I propose to deal more in detail with the experience I have had with mercuriol given in tabloid form. My experiments with this drug, which were conducted at the Bellevue Hospital, New York city, extended over a period of eight and a half months, and during that time I treated 180 cases. Of those entered on my books 74 either did not return after the first visit or were too short a time under observation to be reported. In addition to these I have eliminated 11 others whose irregularity of attendance rendered the records of their cases of little or no use. This leaves the number of cases to be reported on 95. These were under observation for the following periods: over six months, 18; five months, 9; four months, 7; three months, 18; two months, 16; one month, 13; and less than one month, 14. The dosage, regulated either by the point of tolerance being reached or by the disease being brought under control, varied as follows: a quarter of a grain, 1; one half grain, 2; one grain, 18; one and a half grains, 2; two grains, 23; two and a half grains, 3; three grains, 21; four grains, 14; five grains, 8; and six grains, 3. In 64 of those 95 cases the disease was controlled as follows: in two weeks, 8; three weeks, 12; four weeks, 14; five weeks, 6; six weeks, 5; seven weeks, 2; two months, 8; ten weeks, 2; three months, 5; and four months, 1. The remainder I find are marked thus: decidedly improved, 17; improved, 8; no improvement in two weeks, 3; no improvement in four weeks, 1; and no improvement in three months, 2. In regard to the latter cases, it is of course necessary to bear in mind that these were all dispensary patients and it is uncertain whether they took their medicine regularly.

In making these trials my plan was to increase the medicine steadily from one grain until the symptoms were controlled or until there was a slight tendency on the part of the teeth and gums to become tender. If the symptoms were not controlled before the physiological effect of the mercury made itself felt I added small doses of potassium iodide, and in every case where the medicine was taken according to directions, with the exceptions noted above, I succeeded in controlling the symptoms. It will be seen that in some cases three and even four months elapsed before the disease could be said to be thoroughly under control. These, however, were cases in which the drug was given before the eruption appeared, and the patient was not pronounced free of his symptoms until the chancre as well as other manifestations had disappeared, and, as is generally known, a chancre frequently persists for the length of time referred to.

In 67 out of the 95 cases which I have tabulated no other medicine than mercuriol was given. In 15 out of the remaining 28 the addition of iodide of potassium was found to be sufficient to control the disease, while in six others the addition of an iron tonic sufficed for this purpose.

Out of all the cases of which I have examined the records only one suffered from gastric irritation, 11 suffered from diarrhoea, and three lost in weight. The one patient who suffered from gastric irritation could not continue taking the medicine and a change was made. The 11 who suffered from diarrhoea, were relieved by small doses of bismuth subnitrate, continuing their medicine. After a time the bismuth was stopped, the patient continuing on his medicine

with no disagreeable results. One other patient was changed from mercuriol to unguentum hydrargyri because the mercuriol did not control his symptoms even with the addition of potassium iodide. In those cases that lost flesh the dose was decreased and the patient continued on the medicine with no disagreeable results. It may therefore be said that only one case out of the whole number had to be taken off mercuriol. Of all the patients treated it will be noted that there were only two who could not take a grain of mercuriol, the average dose in the other cases being about two grains three times a day. Having used the drug now for about 14 months I recommend that a patient be started on one grain three times a day. On the fourth day he should be given an additional grain, and four days later another grain, the increase being continued at this rate every fourth day until there is slight salivation or slight looseness of the bowels or there begins to be some improvement in the patient. If diarrhoea occurs the patient should be given for a time about 10 grains of bismuth subnitrate three times a day or sufficient doses to control the diarrhoea, the medicine being at the same time continued and possibly increased. After a time it will probably be found that the bismuth can be stopped. Mercuriol, like all other preparations of mercury, will not always control the secondaries, and in such cases potassium iodide should be added, beginning with five grains a day. Probably in the course of a month or so it will be found that the iodide can be dropped and the patient continued on the mercuriol. And here I would emphasise the fact that mercuriol should always be given in pill form—never in solution because of its instability.

It is not necessary that I should report all the cases individually, but I may be allowed to refer to a few of the more remarkable among them and to some of those in which other medicines had failed to control the disease. The following speak for themselves and in my opinion show a very satisfactory record for the drug.

Case 1 had been taking bichloride for one month with very little improvement. Under mercuriol, three grains maximum dosage, the symptoms were under control in five weeks.

Case 2 had been under biniodide of mercury (one-sixteenth of a grain) and potassium iodide (five grains), which caused iodism. His symptoms were controlled in one month under half a grain of mercuriol.

In Case 3 unguentum hydrargyri had failed to control the disease. The patient was put on mercuriol and the dosage pushed up to six grains three times a day. The disease was thoroughly under control in seven weeks.

Case 4 had been on three-eighths of a grain of biniodide of mercury and 20 grains of potassium iodide for two months. The medicine caused nausea and vomiting. Having been put on mercuriol and the dosage gradually increased to five grains three times a day the symptoms were controlled in three weeks.

Case 5 had been taking hydrargyrum bichloride (one-twelfth of a grain) three times a day, under which an eruption on his face had faded, but the eruption on his body still persisted. His symptoms disappeared in two weeks under a maximum dose of three grains of mercuriol three times a day.

Case 6 had been on bichloride of mercury (three-sixteenths of a grain) for three months, in spite of which he had palmar syphilide of an eczematous variety. All appearances of the disease disappeared after he had been one month on mercuriol, his maximum dose being three grains three times a day.

Case 7 had been taking one-quarter of a grain of mercuriol and 15 grains of potassium iodide, with the result that the eruption had decidedly improved, though not to the extent that it should have done. There were thickened red patches on the face, covered with scaly eruptions. The symptoms almost entirely disappeared within three weeks under a maximum dosage of five grains of mercuriol three times a day and 15 grains of potassium iodide.

Case 8 had been treated at the New York City Hospital with inunctions of mercury, under which the eruptions disappeared, but the pains in the bones still persisted. He was relieved in three weeks under a maximum dosage of four grains of mercuriol three times a day.

Case 9 had been taking other forms of mercury for six months. The form which had done him most good was bichloride. Yet one-fifth of a grain did not entirely control the disease. He had been taking that for two months when he was placed on mercuriol. The dosage in his case was

<sup>1</sup> The Treatment of Syphilis, by G. Frank Lydston, Chicago, Professor of Genito-Urinary Surgery, Medical Department, Illinois State University. The Medical Standard, February, 1901.

pushed up to six grains three times a day, and at the end of seven weeks all his symptoms had disappeared.

Case 10 had been taking medicine off and on for two years, but his symptoms never disappeared entirely. After being two weeks on mercuriol (two grains three times a day) with the addition of potassium iodide, all symptoms had disappeared.

I use the drug in my private practice to the exclusion of all others, and my experience is that I get better results in the treatment of my private patients than I do in that of the patients who come to the dispensary. This may be due to the fact that the patients are better nourished and that their stomachs have not been subjected to such severe treatment by the use of alcohol. Possibly, also, it is in some measure due to the fact that they take their medicine more regularly, besides being more careful to follow out the general regimen. I have now under treatment 42 private patients, and a noteworthy circumstance is that in only one of the number has it been necessary to add potassium iodide to control the symptoms. One of these patients had been treated at Hot Springs in 1898. For six months thereafter he saw no signs of the disease; but then, having indulged in a protracted spree, the eruption showed up again, and for the last two years he had been taking all sorts of medicines in the vain effort to get rid of the disease. When he came to me I put him on mercuriol, the maximum dose being three grains three times a day, and at the same time gave him 15 grains of sodium iodide, under which treatment the disease was absolutely controlled in six weeks. Another when he came to me had an immense chancre of the chin, syphilitic angina, macular eruption on the body, and mucous patches on the lip and scrotum. He had been taking hydrargyrum protoiodide for four weeks but was steadily getting worse. I found that the highest dose of mercuriol he could stand was two grains three times a day and that this was not strong enough to control the disease. I therefore changed the treatment to inunction of mercury. Five days later he came back with double iritis and he was given a hypodermic injection of bichloride of mercury. I have not seen him since. As a rule, I find in private practice, as in dispensary practice, that a dose of two or three grains three times a day is the most that patients can stand or require.

In conclusion, I may remark that the treatment of syphilis may or may not be revolutionised by the discovery about which we are now hearing so much, of the coccus which causes the disease; but it appears to me that the probabilities are that, for a considerable time to come at all events, mercury will continue to maintain the position it has held for 400 years as practically the specific for syphilis. Under these circumstances it is of the highest possible consequence that we should ascertain the best method of administering the medicine, and I have found no form so far in which it can be given with such good results as mercuriol.

New York.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### SEQUELA TO A CASE OF RADICAL CURE OF HERNIA.

BY WILLIAM DICK, M.B., F.R.C.S. EDIN.,

MAJOR R.A.M.C., ASSISTANT PROFESSOR OF MILITARY SURGERY, ARMY MEDICAL SCHOOL, NETLEY.

THE following case, I think, is interesting.

A private was operated on at Pretoria on Jan. 28th, 1901, for left inguinal hernia. About ten days afterwards a swelling began to appear in the left side of his abdomen, primary union having taken place in the operation wound; this gradually got larger and he was invalided home, arriving at Netley on May 18th. On examination after arrival there was seen the incision of the operation perfectly healed, and there was to be felt and seen a tumour of about the size of two closed fists, filling the whole of the left side of the abdomen, very hard and with no sense of fluctuation. The man's general condition was good; there was no cachexia or rise of temperature. The diagnosis was that of some deep-seated

inflammatory condition, but still it was thought that it might possibly be a sarcoma. On May 31st an incision was made over the tumour and the muscular wall of the abdomen was cut through; no peritoneum could be recognised. An aspirating needle was then put into the tumour and pushed deeply, when a little pus was withdrawn. The tumour was then cut into; it was very hard, and the relations of abdominal contents were not made out; when the incision had gone to the depth of about three inches a small cavity was found with a little fluid in it. This being explored by the finger a foreign body was felt which was readily extracted by forceps. On examination this was seen to be eight silk ligatures interlocked, such as might be used for ligaturing off the omentum in sections, which no doubt was the case; they were covered with a caseating, crumbling material. A drainage-tube was put in and was retained for 48 hours and then withdrawn. The wound healed slowly with very little discharge. The mass of thickening gradually disappeared, there never being a rise of temperature during the healing process. The man went out perfectly fit, exactly three months after the operation, no trace of the tumour being left.

Netley.

#### A CASE OF TETANUS; USE OF ANTI-TETANIC SERUM; DEATH.

BY T. GRAHAM SCOTT, M.R.C.S. ENG., L.R.C.P. LOND.

A WOMAN, aged 21 years, was first seen by me on Sept. 25th, 1901. Six days previously, on Sept. 19th, a nail had penetrated the right foot just below the ball of the little toe, passing through the sole of the boot and the stocking. After the nail was withdrawn the wound closed and gave her very little trouble for the next three days. On the fourth day it was painful enough for her to keep her foot raised, and in the course of the two days following a small red swelling appeared on the dorsum of the foot above the metatarso-phalangeal joint. On the fifth day after the accident she had aching pains in her back and a stiff neck, and when seen on the sixth day she had well-marked trismus, tonic spasms of the muscles of the neck and back, and occasional slight clonic spasms. The temperature was normal and she took liquid food without much difficulty. Later in the day, at about 6.30 P.M., 10 cubic centimetres of antitoxin from the Institut Pasteur de Paris were injected into the skin of the abdomen, the clonic spasms having by this time become much more severe. At 9 P.M. chloroform was administered and a large area of skin and subcutaneous tissue was removed to a depth slightly greater than that of the original puncture of the nail, both the nail wound and the swelling on the dorsum being taken away. She rallied well from the operation, but as the effect of the chloroform passed off the spasms, both clonic and tonic, returned with much severity. Another 10 cubic centimetres of antitoxin had been injected during the anaesthesia and half a grain of morphia was now given in addition. During the night it was necessary to keep up the administration of chloroform at short intervals (a Junker's inhaler being employed), and towards morning 10 cubic centimetres of antitoxin were again injected, as well as half a grain of morphia. At about 9 A.M. there was considerably less spasm in the muscles of the lower jaw, but elsewhere the spasm had increased, the temperature had risen to 104° F., and the patient already showed considerable signs of exhaustion which increased as the day went on and she died at about 3 P.M. She became much cyanosed towards the end, when brandy was injected and inhalation of oxygen used, but without success.

I must gratefully acknowledge the invaluable help I received from Dr. W. G. Stone and Dr. W. Thornely during the case.

Denmark Hill, S.E.

DEVON AND CORNWALL EAR AND THROAT HOSPITAL, PLYMOUTH.—The fourteenth annual meeting of the supporters of this institution was held on Oct. 4th. The medical report showed that 904 cases had been treated, against 922 in the preceding year. 150 operations had been performed. The financial statement showed a favourable balance of £20. The old hospital in Princess-square was vacated in October, 1900, when the new building in North-street was opened. The committee state that this change has been most beneficial, the old hospital being too small.

### ST. GEORGE'S HOSPITAL.

#### A CASE OF ACUTE HÆMORRHAGIC PANCREATITIS.

(Under the care of Mr. H. W. ALLINGHAM.)

WE publish below two examples of an exceedingly rare disease, acute pancreatitis. One case occurred in St. George's Hospital, London, and the other in the Scarborough Hospital. In each of them the patient was a man who was seized suddenly with a very severe pain in the abdomen and with vomiting; the pain and vomiting continued. In each case a laparotomy was performed—in the former because it was thought that there was intestinal obstruction, while in the latter the true diagnosis was suggested, but there was a suspicion of a perforation. Both patients died, one within 48 hours and the other within 20 hours of the onset of the illness. Such is the typical history of an attack of acute pancreatitis. A sudden and most acute attack of pain in the abdomen accompanied by persistent vomiting arises without apparent cause in a patient, generally a man, who has hitherto been in good health, though in a few cases a history may be obtained of a previous slighter attack. The symptoms simulate intestinal obstruction or a perforative peritonitis, and in consequence in no small number of these cases an abdominal section has been performed. In the vast majority of cases a rapidly fatal result ensues. With our present knowledge it is probably not always possible to diagnose acute pancreatitis, but the great intensity of the symptoms is very suggestive. As to its etiology there are two views now current. One ascribes it to the entrance of bile into the pancreas in consequence of a blocking of the common opening into the duodenum. This view has been chiefly advocated by Halsted and is mainly supported by some experiments on dogs. It is by no means improbable and may account for some of the cases, but there is also much support for the other theory that has been advanced, which ascribes the acute inflammation of the pancreas to the introduction of micro-organisms from the duodenum. In several cases microbes, especially the bacillus coli communis, have been found in abundance in the diseased tissues, and even when allowance has been made for the ease with which bacteria from the bowels invade the neighbouring tissues after death it appears probable that these micro-organisms have a causal connexion with the pancreatic inflammation. For the notes of the following case we are indebted to Mr. Charles R. Keyser, surgical registrar.

A man, aged 26 years, was admitted into St. George's Hospital on Sept. 9th, under the care of Mr. H. W. Allingham. The history was as follows. On Sept. 8th he was seized with a sudden and severe attack of vomiting, followed almost immediately by excruciating pain in the abdomen, chiefly on the left side, which had continued until admission. The vomiting had also persisted and was almost constant. The bowels were absolutely constipated, neither flatus nor faeces having been passed; there was also pain on micturition. The bowels were opened for the last time on Sept. 6th. The patient stated that one year previously he had suffered from a similar though milder attack. The temperature was 98.6° F. and the pulse was 120, and he looked very ill. There was no cyanosis of the face or of the abdominal wall. The abdomen was slightly distended, chiefly around the umbilicus, was quite soft, and moved slightly on respiration in a quivering sort of way. Pain was present on respiration and on palpation, especially on the left side of the umbilicus, where some resistance was felt. There was no tenderness in the right iliac region and there was no jaundice. A diagnosis of acute intestinal obstruction was made and immediate operation advised.

Gas and ether, and subsequently chloroform, having been

given, Mr. Allingham opened the abdomen in the middle line below the umbilicus. On opening the peritoneum some blood-stained fluid escaped, but no other abnormal condition could be felt. There was no peritonitis and the intestines were but slightly distended. The skin incision was enlarged upwards and the intestines were examined from the jejunum to the rectum; there was no obstruction. Acute hæmorrhagic pancreatitis was immediately thought of, but the patient was not in a condition to stand any prolongation of the operation; before closing the abdomen it was noticed that the omentum was much redder than normal. On the next day the patient was distinctly better, the pain being less and the vomiting having stopped, but the pulse was 156 and the temperature was 97.8°. He complained of thirst and was unable to pass his urine. The abdomen was slightly distended and did not move on respiration; the bowels had not acted nor had any flatus been passed in spite of enemata and the passage of a rectal tube, &c. It was obvious, therefore, that the improvement, if any, in his condition was only in relation to subjective symptoms. He gradually became worse and died early the next morning.

*Necropsy.*—Dr. R. S. Trevor, assistant curator of the museum, who made the post-mortem examination, thus describes the condition found after death. There were 10 ounces of blood-stained fluid in each pleural cavity. Both lungs were sodden with blood and serous fluid and there was much frothy mucus in the tubes. The pericardium was healthy. There was a small amount of blood-stained fluid in the peritoneal cavity and there were a few clots in the pelvis. There was no obstruction or strangulation of the intestines. In the neighbourhood of the pancreas the fat around and in the mesentery was very blood-stained. The pancreas was much enlarged and there were a few hæmorrhages in the liver. The gall-bladder contained no stones and the bile was very fluid and escaped freely from the papilla duodenalis. The pancreas was increased in thickness to nearly four times its usual size; this increase mainly affected the body. The surrounding fat was deeply blood-stained and in places was softened into red masses of a jelly-like consistency with a very offensive odour. There was much matting together of the parts, the pancreas being firmly adherent to the stomach as well as to the spleen and left kidney by a mass of tissue much infiltrated with blood. There were numerous areas of fat necrosis in the vicinity of the pancreas as well as in the omental fat. On cutting into the pancreas the gland substance was seen to be much altered, more particularly in the body of the organ; in the head and tail lobulation was still present. The tail on section was uniformly red in colour; the head looked nearly normal but there were a few darker areas to be seen. In the body the normal lobulation was absent and the gland substance was here of a greyish-black colour with irregularly scattered islands of a yellowish tint. It was softened and pulpy; the duct of Santorini opened into the duodenum by a separate papilla situated just above the biliary papilla. There was no calculus in the ampulla of Vater, but on squeezing the head of the pancreas white cheesy material escaped from the biliary papilla and the papilla for Santorini's duct. The splenic vein was dilated and as it crossed the tail of the pancreas there was adherent ante-mortem clot in it, but the lumen was not completely occluded by clot. Dr. H. R. Spitta, assistant bacteriologist to the hospital, reported that cultures taken from the substance of the most affected area of the pancreas grew typical bacillus coli communis.

*Remarks by Mr. KEYSER.*—Acute hæmorrhagic pancreatitis is comparatively so rare a disease and simulates intestinal obstruction so closely that every case ought to be recorded, so that by paying attention to the symptoms and course of the malady it may be possible in the future to differentiate the two conditions. A good many cases have already been reported, but the diagnosis has hardly ever been made with certainty before operation or death, which last is unfortunately the usual result of the disease. Halsted<sup>1</sup> has reported a case and lays especial stress on two symptoms:—viz., excruciating pain in the abdomen, exceeding that produced by any other disease, and cyanosis, both of the face and of the abdominal wall, so that an imprint of the fingers can readily be obtained on pressure. Only the former of these two indications was present in the case described above. The probable cause of the disease is as Halsted and Opie suggest—retrojection of bile into the pancreas produced by the impaction of a very small calculus in the ampulla of

<sup>1</sup> Johns Hopkins Hospital Bulletin, 1901, Nos. 121, 122, and 123.

Vater. As is well known, the common bile-duct usually joins the pancreatic duct (duct of Wirsung) a short distance from the duodenum, and the two channels form a slightly dilated ampulla before opening on the surface of the second portion of the duodenum. This orifice, Hyrtl<sup>2</sup> states, is narrower than the lumen of the gall-duct at any point, or is at least less distensible, so that gall-stones often remain impacted at this point.

The conditions necessary for the production of acute hæmorrhagic pancreatitis by a calculus are set forth by Halsted as follows. 1. In order that bile may be retrojected into the pancreatic duct the stone must be (a) too small to occlude the pancreatic duct or to interfere with the force of the jet and at the same time (b) too large to pass the ampulla. 2. One calculus would be more likely to cause the pancreatitis than several, for other stones in the duct, unless very small, would weaken the force of the bile-spurt which drives the ball-valve against the papillary orifice. 3. The gall-bladder must be normal or nearly so—not thickened, shrunken, or weakened by inflammation. Thus a small calculus in the ampulla of Vater converts the two ducts into a continuous channel, while a large stone might simultaneously obstruct the duodenal orifice of the diverticulum and the orifices of the ducts which enter it, thus damming back bile and pancreatic juice upon their respective glands. Opie, who performed the necropsy on Halsted's case, made the following experiments on dogs: in five instances the duodenum was opened and the duct was injected with bile, varying from 2.5 to five cubic centimetres. In two other cases the duct was opened, injected with bile, and ligated. In all hæmorrhagic pancreatitis and fat necrosis were produced and verified by examination post mortem. If the theory set forth above is correct, and it certainly seems probable from Opie's experiments, the obvious treatment is to cut down on the duodenum and to remove the calculus from the ampulla of Vater. In the case I have described no calculus was found, but it must always be so exceedingly small that unless special precautions are taken it may very readily be overlooked or washed away. I am indebted to Mr. Allingham for permission to record the case.

### SCARBOROUGH HOSPITAL.

#### A CASE OF ACUTE HÆMORRHAGIC PANCREATITIS.

(Under the care of Dr. G. B. HUNT.)

For the notes of the case we are indebted to Dr. C. H. Brodribb.

A man, aged 51 years, had been quite well until the morning of August 15th, when shortly after eating his breakfast he went to his work feeling "unwell"; soon he became worse, with severe abdominal pain and vomiting, and was taken home. A medical man was sent for, who saw him for the first time at 3 P.M. and again at 8 P.M., when finding that the vomiting was more frequent, that the patient was becoming collapsed, and that there was some slight dulness in the left flank he asked another practitioner to see him. A suggestion of perforated duodenal ulcer was made and the man was advised to go into hospital. His bowels had been opened during the afternoon. The previous history was good, the patient never having had any illness that he knew of.

The patient was admitted into the Scarborough Hospital about 10 P.M. The temperature was 96° F., with a clammy skin and small, feeble, regular pulse of 88. He was quite conscious; indeed, he was very bright mentally considering his collapsed condition. He was vomiting ill-smelling bile-stained fluid and complaining of pain in his abdomen, chiefly in the umbilical region. Examination of the abdomen showed it to move well with respiration and to be regular in contour. There was but little tenderness and no rigidity, tumour, or enlargement of any organ could be made out. Percussion showed dulness in both flanks which was moveable with position. There was no tympanites or displacement of liver dulness. A catheter passed before admission drew off normal urine. He was watched for some 50 minutes, when the dulness in the flanks becoming obviously increased and his pulse smaller—at 95—Dr. Brodribb telephoned his condition to Dr. Hunt who, after seeing him, suggested an acute pancreatitis.

An operation was at once performed, the abdomen being opened in the middle line from the ensiform cartilage to the

umbilicus. A very large quantity of deeply brown-stained fluid at once escaped. The omentum was examined and was found to show particles of necrosed fat all over it; also the appendices epiploicæ were found to be necrosed. A large hard mass could be felt in the region of the pancreas. The stomach, duodenum, and other organs were apparently normal. The patient's condition being bad the abdomen was rapidly washed out with hot normal saline solution and sewn up. He was put back to bed very collapsed and lived about three hours.

*Necropsy.*—The post-mortem examination was confined to the abdomen. The fat throughout the abdomen showed necrosis in patches, also small patches were found on the parietal peritoneum. These patches varied in size from that of a pin's head to that of a thumbnail and were firm and of a glistening, dark greyish colour. The pancreas was much enlarged, the head being as much as two and half inches thick and dark red from the extravasated blood. The head was the part chiefly affected, the process becoming less severe towards the tail which at the tip was of its natural colour. There was no peritonitis. The spleen, liver, duodenum, and other organs seemed to be normal.

*Remarks by Dr. BRODRIBB.*—The extreme rapidity of the onset and collapse, the rapid increase of dulness in the flanks with the absence of tympanites, signs of peritonitis, or localising symptoms seemed to me to be inconsistent with the diagnosis of any one of the more common acute abdominal conditions calling for laparotomy, while on opening the abdomen the condition of the omentum at once pointed to pancreatic disease, which was confirmed by feeling the swollen pancreas. The great quantity of brown-stained fluid effused was very striking. I find in some cases previously recorded in THE LANCET that the colour of the fluid is said to be due to bile. I thought when I saw it that it was due to blood in which the pigment was changed to methæmoglobin, but unfortunately I was unable to test it. The pancreas and omentum were preserved by the formalin and glycerine method, which, it is interesting to note, turned all the patches of fat necrosis coal black. I have to thank Dr. Hunt for his kind permission to publish the case.

## Medical Societies.

### MEDICAL SOCIETY OF LONDON.

#### General Meeting.—Presidential Address.

A MEETING of this society was held on Oct. 14th, the chair being occupied at first by Mr. J. H. MORGAN and subsequently by Dr. W. H. ALLCHIN, the outgoing and incoming presidents respectively.

At the general meeting of the society which immediately preceded the ordinary meeting the Treasurer's report and balance-sheet were presented and adopted.—A vote of thanks to the Treasurer, to the retiring President, and to the Secretaries was proposed, and Mr. J. H. MORGAN and the retiring Secretary, Mr. F. C. WALLIS, replied.

The incoming President, Dr. W. H. ALLCHIN, then took the chair, and after some preliminary remarks on the past and future work of the society, read the Presidential Address on the Responsibility of the Organism in Disease. He said that among the widest spread inclinations of the human mind, however uncultivated or unlearned, was the desire to ascertain the cause of such phenomena as came under observation. That this was the case in respect to disease, so far as the laity were concerned, was well known to most of them, and their patients were generally fully satisfied by ascribing the malady to "a chill" or in finding some ancestor supposed to have been similarly affected. This subject was chosen, for there were indications that in the far-reaching and all-important extension of their knowledge by the discovery of the part played by microbes in the production of morbid states the personal factor was running the risk of being somewhat lost sight of. The President then dealt with the present conception of the nature of life, and he pointed out how the earliest recorded Hippocratic teaching was strangely similar to that of the present day. In considering the environment he said that although the main purpose of his remarks dealt with the share taken by the individual in the causation and manifestation of disease, yet it was necessary to say a few

<sup>2</sup> Handbuch der Topographischen Anatomie, Vienna, 1882.

words upon the external conditions to which every living being was subject. For the present purpose the environment factors might be grouped as follows. 1. Violent contact, represented by blows, injuries, and laceration of internal structures by foreign bodies, such as calculi and the like. 2. Another group of external conditions was represented by such natural agents as heat, light, electricity, and as barometric pressure and gravity, and such subsidiary conditions as relative humidity or dryness of the atmosphere. 3. The third set of conditions were those which produced their effects in virtue of the chemical changes which they set up, and these included modifications of the ingesta and perversion of the alterations which they might undergo in the process of digestion and absorption—in fact the whole class of substances denominated poisons. As causes of disease these bodies were well known, and the recent development of bacteriology and a knowledge of the toxins elaborated by micro-organisms had widely extended their acquaintance with the agents of this group. Very striking as showing the variable composition and constitution of bioplasm were the effects of poisons, some of which were quite innocuous to some cells whilst violently toxic to others. In attempting to comprehend, therefore, the effects of external agencies, however simple or however complicated they might be, they had also to reckon with the responsive capacity of the living organism. How was it, for instance, that the exposure to cold and wet would in several persons under similar circumstances bring about very different forms of disease? Whilst one developed acute nephritis another was attacked with acute pneumonia; another had a rheumatic attack, and the fourth might not suffer at all. Great and important as was the discovery of the microbic cause of tuberculosis it would be long before those who had had any extensive experience of the ravages of that disease would admit that the bacillus tuberculosis was the only thing to be kept in view either in the causation, the prevention, or the treatment of the malady; and at the present day, with the vast impetus that had been given to the investigation of external conditions by the discovery of the bacterial origin of many diseases, there was a fear that the pendulum would swing too far in that direction with the result that too little attention would be paid to the individual and the share he took in the origination of the disease, or what was more important the part he should be made to play whether in the prevention of disease or in the treatment of it when existent. If now they turned to consider what bodily states were to be regarded as heritable they would find that the number was very considerably less than was formerly supposed and that the transmissibility even in those cases which were accepted was not so potent as was thought. In other words, it was less the disease itself than a predisposition or tendency towards it, often requiring for the development of the malady a suitable conjunction of external conditions, in the absence of which the individual escaped, though this could not always be so, for the tendency might be so strong as to assert itself in spite of the most favourable environment. Prominent among those conditions which tended to recur in successive generations were longevity and the reverse. States which insensibly departed from the healthy type, reaching to a degree in which the well-being was interfered with, were represented by an undue formation of fat, obesity, or an exceptional leanness, and such states were notoriously prone to characterise the members of families over many generations. A third group comprised such essentially nutritive disturbances as gout and diabetes. Possibly even the more marked illustrations of diseases appearing in the offspring similar to those from which the parents suffered were to be found among nervous maladies. As further illustrating the responsibility of the organism itself in the occurrence and manifestation of disease might be mentioned the undoubted influences exerted by age and sex. It was much to be desired that that society should prosecute some collective inquiry into the incidence of disease in successive generations. But in endeavouring to form some estimate of the share taken by the individual in the determination and manifestation of disease they were dealing with a subject that was essentially practical in all its bearings, however speculative might be the basis which subtended the application. The correct estimation of the value of the facts ascertained when inquiring into the family history and life-history of patients depended upon some knowledge of the workings of the organism in response to external stimuli, and of such inherent qualities and capabilities as the patient might possess. Whilst it might seem but little toward the

framing of a diagnosis in the use of that term which was restricted to the mere naming of the disease, in a wider sense of comprehending the real nature of the case it was all important, and underlying as it did prognosis, the estimate of the individual resistance to the disease and furnishing therein the only rational plan of treatment, its study could not be too sedulously cultivated. He would claim, therefore, that he had not, after all, wandered far afield from their legitimate occupation and whilst *dulce est desipere in loco* he ventured to hope that his dissipation in generalities had not been out of place.

A vote of thanks, proposed by Dr. MITCHELL BRUCE and seconded by Mr. EDMUND OWEN, was accorded to the President for his address.

## PATHOLOGICAL SOCIETY OF LONDON.

*Sylvian Aneurysm.—Hæmorrhagic Myositis in Enteric Fever.—Pleuro-Esophageal Fistula.—Imperforate Pharynx.—General Dilatation of the Aorta with Dissecting and Sacculated Aneurysms.—Hydatid of the Gall-bladder.—Exhibition of Specimens.*

A MEETING of this society was held on Oct. 15th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. WAKELIN BARRATT and Dr. RICHARD M. RALPH exhibited a Right Sylvian Aneurysm lying upon the island of Reil and situated on the main trunk opposite the origin of the ascending parietal branch, the lumen of which was narrowed. The aneurysm, which was of the size of a pea, was met with in a female patient, aged 38 years. Left-sided weakness was noted during life, but no cortical softening was present, nor did the aneurysm rupture, death occurring from an intercurrent condition. No cause could be assigned for the aneurysm, the arteries at the base of the brain being elsewhere healthy. Endocarditis was absent and no evidence of syphilis was obtainable.

Dr. F. W. ANDREWES described a case of Muscular Hæmorrhage in Typhoid Fever dependent upon secondary infection with streptococcus pyogenes. The patient was a man, aged 18 years, admitted to hospital during the third week of a severe and typical attack of typhoid fever. He had chronic double otitis media. He died during a relapse on the fifty-second day of his illness. Two days before death there was pain in the left thigh, followed by a considerable swelling, suggesting deeply-seated fluid. The lesions found post mortem were those characteristic of typhoid fever. There was no endocarditis, and the vessels, including those of the affected limb, were natural. The swelling in the left thigh was due to diffuse extravasation of blood into the substance of the quadriceps extensor cruris, especially the vastus externus. There was no rupture of the muscular fibres. No other muscles were found affected. The affected muscle showed a moderate degree of Zenker's waxy, or hyaline, degeneration, with profuse extravasation of blood. It contained enormous numbers of streptococci and no other organisms. Streptococcus pyogenes was isolated from it in pure culture, and the same organism was found in the heart's blood and spleen, mingled with other bacteria. There was, therefore, good reason to believe that the hæmorrhage was associated with this secondary infection rather than with the primary typhoid fever. The affected muscle was exhibited, together with a teased preparation and microscopic sections showing the distribution of the streptococci and the characters of the degenerative changes in the muscle-fibres. Whether or not the lesion was a true myositis was open to discussion, though this was probably the case. Zenker, Trousseau, and others regarded such cases, which seemed to have been commoner then than now, as due to rupture of the muscle due to a primary waxy degeneration, which Zenker showed to be common in typhoid fever apart from muscular hæmorrhage. More recently it had been held by Arnold, Wehl, and others that waxy degeneration was more often a sequel than a cause of rupture and hæmorrhage, and this seemed to be the more reasonable explanation in the present case, in which the hæmorrhage was evidently septicæmic in character. —Dr. W. CAYLEY said that the present case supported the view that the hæmorrhage was due to streptococcal infection and not directly to the typhoid bacillus. He had seen more cases of hæmorrhage into muscles in typhus fever than in typhoid fever. He did not consider that waxy degeneration of the muscle was peculiar to typhoid fever, for it was often

present in cases of advanced phthisis. Although all the appearances commonly associated with inflammation might not be present in the muscles into which hæmorrhage had occurred, yet he was of the opinion that the condition was an inflammatory one.—Dr. H. M. FLETCHER pointed out the difficulty of making the examination of the muscles sufficiently complete so as to form any accurate idea of the relative frequency of the condition in typhoid fever.—Dr. NORMAN DALTON said that they should take the clinical evidence in conjunction with the pathological, and in this case there was evidence that the hæmorrhage had existed for at most 48 hours; had this been secondary to streptococcal infection it was certain there would have been more evidence of inflammation, and he thought it probable that the streptococcal infection occurred after the hæmorrhage.—Dr. W. BULLOCK was also of the opinion that the streptococcal infection was secondary to the intramuscular hæmorrhage. He also pointed out that Zenker's degeneration could be produced by ligation of a vessel supplying a muscle.—Dr. ANDREWES, in reply, said that although it was difficult to prove he was of the opinion that the streptococcal infection had some causal relation to the production of the hæmorrhage.

Dr. HUGH THURSFIELD described a case of Pleuro-oesophageal Fistula in a boy, aged four and a half years, who was the subject of a neglected empyema which had for six weeks been slowly discharging from sinuses situated in the front of the chest. After resection the pleural cavity did not drain very well, and about one month after operation food taken by the mouth began to pass out of the resection wound. The boy died a fortnight later. At the post-mortem examination a small communication was found to exist between the oesophagus and the right pleural cavity opposite the head of the third right rib. There was no amyloid disease, and no evidence of tubercle, caseous glands, or foreign body was found. The conclusion was that ulceration took place in the pleural cavity, leading to softening and perforation of the oesophageal wall.—Dr. A. F. VOELCKER referred to the fact that caseous lymphatic glands might soften and discharge into the bronchus or oesophagus and possibly also into the pleura. In a similar case which he had reported he had suggested that this was the probable explanation of the condition, and he thought the same explanation might hold good in the present case.—Dr. EDMUND CAUTLEY referred to a case in which he had diagnosed enlargement of the mediastinal gland. An abscess formed in the thorax which was drained and the child made a good recovery. He thought that a caseous gland was the most probable explanation in this case.

Mr. S. G. SHATTOCK described an example of Imperforate Pharynx in an agnathous lamb. Although imperforate rectum was so common in the human subject apart from accompanying grosser defects, it was remarkable that the persistence of the primitive condition (in which the gut terminated blindly at either end) was one of the rarest of malformations affecting the upper part of the alimentary canal and had never been met with except in conjunction with ill-development or absence of mandible or highly marked arrests in the cranio-facial axis, synotia, and cyclocephalus. Congenital atresia of the oesophagus was fairly frequent, but this had nothing in common with imperforate pharynx and was in no sense the homologue of imperforation of the rectum. As Mr. Shattock had pointed out, atresia of the oesophagus was invariably situated opposite the lower end of the trachea and was a condition acquired during fetal life and probably in some way connected with the voluminous growth of the lungs and lower part of the trachea as a diverticulum from this spot of the anterior wall of the oesophagus. In imperforate pharynx the disposition corresponded with what would arise from the abnormal persistence of a normal phase of development. His researches had shown that the stomodæum formed scarcely any of the buccal cavity; that the whole of the tongue was formed from the floor of the blind pharynx; and all this was shown in the specimen he exhibited. The lower jaw was wasting, but the stomodæum was represented in part by an area of mucous membrane covering the under side of the exposed palate and in part by the nasal cavity; there was no communication, however, between these parts and the post-jacent pharynx, from the floor of which a well-formed tongue projected.

Dr. FLETCHER showed a specimen of General Dilatation of the Aorta with Dissecting and Sacculated Aneurysms which Simulated New Growth of the Kidney. The patient, a man, aged 31 years, was on two occasions

in St. Bartholomew's Hospital, during which periods he suffered from profuse hæmaturia and subsequently from hæmoptysis. There was a large, hard nodular tumour on the left side of the abdomen. He presented signs of double aortic disease. At the necropsy the whole of the aorta was enormously dilated; there was a large dissecting aneurysm involving the arch with a sacculated aneurysm on the descending thoracic portion. The abdominal tumour was formed by an aneurysm extending from the level of the diaphragm to the bifurcation, which was filled with firm clot. It lay in front of the left kidney.

Mr. L. H. MACGAVIN showed a specimen of Hydatid of the Gall-bladder; the patient had had a swelling in the abdomen for three years. The abdomen was opened and the hydatid was removed. Hydatid of the gall-bladder, apart from cases in which the liver was also invaded with hydatids, was rare, some three cases only having been reported.—Dr. NORMAN DALTON, who was present at the operation, said that the cystic duct was cut across and ligatured at the time of the operation and therefore there could be little doubt that the hydatid was in the gall-bladder.—Mr. SHATTOCK said that he had carefully searched the specimen for the cystic duct but had been unable to find it. He was of the opinion that the cyst was a pedunculated hydatid and not the gall-bladder, and this was further borne out by the microscopical examination of the wall. He suggested that the subject should be referred to the Sectional Committee for further investigation.

Dr. THURSFIELD showed two card specimens: (1) Cerebellar Tumour arising from the Ependyma; and (2) a case of Porencephaly.

Dr. LEE DICKINSON showed a specimen of Lymphadenoma of Bone.

## CLINICAL SOCIETY OF LONDON.

*Painful Condition of the Twelfth Pair of Ribs.—Displaced Strangulated Femoral Hernia.—Treatment of Wounded Joints.—Surgical Treatment of Ascites.*

A MEETING of this society was held on Oct. 11th, Mr. ARTHUR BARKER, Vice-President, being in the chair.

The new volume of the society's Transactions was brought before the meeting. Mr. BARKER mentioned that the surplus volumes of the series were offered to members at a reduced rate.

Mr. J. JACKSON CLARKE read notes of a case of Painful Condition of the Twelfth Pair of Ribs. The patient was a nursemaid, aged 19 years. She first came for treatment on account of a forward bend of the spine (kyphosis), accompanied by a painful backward projection of the tips of both twelfth ribs. The former was corrected by the use of an antero-posterior support, but the condition of the twelfth ribs remained unchanged, any forward pressure upon them causing great distress. The pain was deeply-seated and Mr. Clarke referred the abnormal condition to rheumatoid inflammation of the costo-vertebral joints. So long as the spinal support was worn it sufficiently protected the ribs from pressure; when, however, the time came for leaving off the support the patient found that she could not bear the pressure of her dress upon the ribs. An attempt was made to palliate the condition by making apertures in the patient's stays, but this did not succeed. The patient was therefore advised to undergo an operation for the removal of as much of each twelfth rib as could be taken away without incising the erector spinae. The operation consisted of cutting down on each bone in turn and removing one inch, including the cap of cartilage, with the periosteum. The deep parts were carefully drawn together by fine silk sutures before the skin-wounds were closed. Rapid healing ensued. There was no subsequent bulging at the site of the operations, and the pain was at once relieved and had not since returned. Mr. Clarke mentioned another case in which one of the twelfth ribs was the seat of occasional swelling, accompanied by great pain. The patient was a woman, aged 40 years, and the swelling was due to inflammation about the junction of the cartilage and the bone. In this case relief was obtained by an abdominal belt made with a recess to receive the tip of the rib.—Mr. BARKER congratulated Mr. Clarke on his paper. The condition must be rare and was outside his experience.—Dr. WILLIAM EWART was glad that the subject had been approached by the surgeons. He wished to refer to a condition which he had described as "acrochondralgia." It

was a very localised symptom and was due to a variety of causes; certainly it was aggravated by corsets unless one of the bones was broken. He would like to hear from Mr. Clarke what evidence there was of definite osteo-arthritic nature of the mischief in the costo-vertebral joint.—Mr. CLARKE, in reply, did not think that tight-lacing had anything to do with the production of the condition in his case. He thought that it was probably due to the action of the muscles on a weakened articulation. He took away about half an inch. The cases referred to by Dr. Ewart were interesting but were not parallel. He referred to the case of a woman, aged 40 years, who had acute pain in the tenth rib, which, when first seen, in the interval of the attacks, presented nothing abnormal, but later, during an attack, he found a swelling at the end of the rib of the size of a filbert. The pain was relieved by a suitable support.

Mr. THOMAS BRYANT read the notes of a case of Displaced Strangulated Femoral Hernia. The patient was a married woman, aged 32 years, who had been troubled with a femoral rupture for about five years but had not worn a truss. The rupture had come down every now and then, and she said that she had never experienced difficulty in its reduction, although on questioning her husband later it appeared that she had often used much force in reducing the rupture, and particularly on March 29th, two days before her present illness. Her illness commenced as a "bilious attack," and it was not till three days passed and the vomited matter had become stercoraceous that the possibility of the case being due to her reduced hernia had been realised and Mr. Bryant's advice sought. When seen on April 3rd she was in an extreme state of collapse and it was clear that life could not be saved. Her abdomen was distended but not tense and there was no swelling in the right femoral region, which was given as the seat of her hernia, although pressure with the pulp of the index finger over the right femoral canal elicited pain. An exploratory operation in the femoral region was, however, determined upon, based upon the established practice of first examining in every case of intestinal obstruction associated with a hernia the region in which a hernia existed. The operation was carried out in the usual way and the obstruction relieved. The operation was completed, but the patient sank as expected and died a few hours later. A partial post-mortem examination could alone be obtained, but from the specimen which was secured by Mr. C. R. C. Lyster, the house surgeon of Bolingbroke Hospital, and which, as dissected and mounted by Mr. Shattock, was now in the Museum of the Royal College of Surgeons of England, it seemed clear that the sac of the femoral hernia had been forced through a rupture of the femoral sheath at its lowest part or apex into the connective tissue of the thigh on the inner side of Scarpa's triangle, and that the seat of strangulation was at the neck of the sac, which was not, as was usually the case, at the femoral ring, but at the orifice of the femoral sheath through which the hernial sac had been forced. Mr. Bryant remarked that the case which he had read was clearly a very unusual one. Indeed, he had never seen or read of a femoral hernia being displaced as this must have been into the fatty connective tissue of the inner side of the thigh, with the seat of strangulation at least one and a half inches below the femoral ring and situated at the mouth of the opening in the femoral canal through which it was probably forced. Had there not been a distinct history of an old femoral hernia in this case there would not have been any local indication to lead the surgeon to suspect that the intestinal obstruction which the symptoms suggested was due to such a cause, for there was a total absence of all swelling, and the sign of pain on pressure over the femoral canal stood alone. Under these circumstances an abdominal operation might have been undertaken, and if so it would have been useless, for the seat of strangulation was outside the abdominal cavity, and could not by such a measure have been relieved, for it must be emphasised that during the operation, when the femoral sheath was first opened, the bowel which was in it was not seen, for it rested in a bloodless and collapsed condition upon its posterior wall, and it was not till the crural ring was enlarged that it made itself manifest by bulging forwards and arching downwards from the femoral ring to the seat of its stricture and the apex of the femoral canal. This portion of exposed intestine was quite healthy looking and pale and contrasted strongly with the deeply congested bowel which was subsequently withdrawn from the displaced hernial sac. The force employed had brought about primarily a rupture

of the femoral sheath at its lower end and secondarily the gradual herniation of the femoral sac with its contents into the space in the connective tissue as demonstrated by the dissected specimen. This case was an example of a third variety of displaced femoral hernia. The first was the well-recognised form in which the small strangulated femoral hernia with its sac might be pressed out of sight and reduced, still strangulated behind the abdominal parietes, the one of "reduction *en masse*"; the second was where a large femoral hernia by some rupture of its sac might show itself as a tumour in the subcutaneous connective tissue above or below Poupart's ligament; and the third as a displaced hernia following the course of this case. In the many varieties of "displaced inguinal" hernia which had been described, and particularly by Mr. J. Birkett and Mr. Bryant in his "Practice of Surgery," the injurious effects of misapplied force had been fully recognised; indeed, it seemed probable that in all the varieties of displaced inguinal hernia it should be regarded as their probable cause. The case illustrated the evils of forcible taxis.—Mr. BARKER said that he had never met with exactly this variety of hernia. He raised the question whether taxis ought ever to be applied to a strangulated hernia, a practice which he had abandoned, he believed, with advantage. He thought that if this view were endorsed by a surgeon of Mr. Bryant's experience it might produce a good effect in practice, both private and in hospital, where he had often seen violent taxis applied in such cases to the detriment of the patient.—Mr. BRYANT, in reply, said it was clearly a femoral hernia, though when he first opened the sac the crural canal appeared to be empty, the intestine being collapsed and flat. He was disposed to agree with Mr. Barker in his remarks on taxis, at any rate in regard to femoral hernia, but an inguinal hernia was rather different. He would not, however, employ taxis even in the latter unless the patient was under an anaesthetic, and then only very gently. Anything like violence would be iniquitous. In a scrotal hernia the neck was usually very large, and it was much mixed up with omentum, so that the bowel was not so readily injured as in a femoral hernia.

Mr. CUTHBERT S. WALLACE read a paper on the Treatment of Wounded Joints. He remarked that wounds of joints fell into three categories: (1) those in which the joint injury was complicated by compound fracture and in which the wounded joint was the lesser injury (the treatment of such a case depended more upon the complicating wounds than on the wound of the joint); (2) wounds, or probable wounds of joints; and (3) doubtful wounds of joints, such as perforating or punctured wounds. The notes of three cases of the second group were read: one of these ended fatally, one recovered with a stiff knee, and the other with a moveable joint. The treatment of such injuries was then discussed and it was maintained that the cleansing of the wound must be mechanical, and therefore that all dirty tissue should be cut away with knife or scissors, and a douche if used was only beneficial because it removed fragments of dirt or soiled tissue; it was, therefore, sufficient to employ sterilised saline fluid, and antiseptic solutions were unnecessary. A search for a wound into the joint was not recommended, as if found it was unlikely that much good could be done, and if an opening was accidentally made into the capsule a serious harm might result. If the opening into the joint was obvious it was recommended to close the capsule without irrigation of the joint and to await developments. The notes of five cases of punctured wounds of joints with resulting infection were then read. In four instances practically full movement was obtained and in the fifth movement was limited to about one-quarter that normally present. It was thought that the best treatment of such cases was arthrotomy with sterilised saline solution and suture of the joint cavity. This process could be repeated once or twice if the condition required it. After this, if the temperature remained high, the incision into the joint could be left open and lavage practised daily. Mr. Wallace thought that if the infection reached the peri-articular tissue surgery could do but little save opening any abscess that might form or ablation of the limb. Drainage by means of tubes through the joint or continuous irrigation were likely to do more harm than good.—Mr. BARKER agreed that in these cases antiseptics were not only useless but were often positively injurious. For many years he had employed only irrigations of normal saline solution whereby his results had improved. With this treatment he had obtained very good movement even in very

severe cases—gonorrhoeal arthritis, for instance. He wished to lay down the principle that once a joint was infected it could not be disinfected.—Mr. F. C. WALLIS observed that it would be an advantage to have some definite plan of treatment laid down for these cases. Mr. Wallace's cases resembled those which he had brought before the society in 1898. These perforating wounds of joints if they became at all inflamed might be treated by a fairly free opening and drainage, a plan which had given him excellent results. In one case the knee-joint was exposed for six weeks, yet movement, though limited, was good. The introduction of drainage-tubes into the interior of the joint and the use of antiseptics were likely to bring about absolute ankylosis with protracted recovery.—Mr. F. C. ABBOTT pointed out that it was long the practice in suppurative peritonitis to make a small opening and to irrigate the cavity, and that treatment was generally agreed to be of the most hopeless kind. It was only recently that they had made large incisions and turned out the intestines so as to enable them to cleanse the entire cavity, and they had thereby got improved results. As to the treatment of adhesions in joints, he asked whether forcible movements were likely to be of more benefit than could be obtained by simple massage.—Mr. WALLACE, in reply, thought that where there was a large outer wound and a small wound into the joint it was worth while giving the joint a chance. He insisted on the fact that cleansing the joint was a purely mechanical procedure and it was no good trusting to antiseptics. He did not think that forcible movements could do any good.

Mr. C. W. MANSSELL MOULLIN read a paper on the Treatment of Ascites by Suture of the Omentum to the Anterior Abdominal Wall. He read the notes of five cases of ascites dependent upon cirrhosis of the liver in which he had adopted this procedure with the view of establishing a collateral circulation, after the Drummond-Morrison method. Two cases died, one four weeks after the operation from pleurisy and the other one week after from exhaustion. In both of these the operation had been performed too late. The disease was too far advanced and there was no time for the anastomotic circulation to be developed. In one of the patients, who weighed over 15 stones, the liver weighed only three and a quarter pounds. The three other patients were discharged from hospital relieved. One could not be traced. The two others were alive and at work at the present time, two years after the operation. Mr. Mansell Moullin pointed out that so far as ascites was of mechanical origin there could be no question that the operation was capable of giving relief. There was the clinical evidence that a certain proportion of patients suffering from cirrhosis of the liver who were treated by repeated tapping got well at last, even after they had been tapped 20 or 30 times, and there was the pathological evidence of the enlargement of the ordinary anastomotic channels between the radicles of the portal and systemic circulations and of the very great development of accessory channels in the freshly formed adhesions, as, for instance, was shown most plainly by one of Morrison's cases which died from an operation for ventral hernia two years after the omentum had been sutured. If, on the other hand, the ascites was held to be not mechanical, or not wholly mechanical, in origin, but to be due to the impairment in activity of the liver cells caused by defective blood-supply, it was equally the fact that the only hope of restoring the activity of those cells and giving them a better blood-supply consisted in establishing a number of vascular adhesions between the contiguous surfaces of the liver and the abdominal wall at a period when compensatory growth was still possible. Mr. Mansell Moullin pointed out that the operation was not, if the cases were properly selected, one that was attended by any serious degree of risk. It was true that the mortality, as judged by statistics, had been very high up to the present, but this was always the case with new operations and was due to the fact that many of the cases were unsuitable, often because of disease in other organs of the body, and that there was a tendency to look upon the operation as a last resource, one only to be performed when everything else had been exhausted. With better selection and earlier operation there was no reason why the mortality should be appreciably higher than that of exploratory laparotomy. So far as technique was concerned, a median incision above the umbilicus was the most convenient and gave least trouble afterwards. Through it the whole of the upper surface of the liver could be reached and the omentum could be fixed to the abdominal wall by sutures passed from its peritoneal surface. Drainage was unnecessary and might be dangerous, as offering additional risk of sepsis. The fluid always collected again, but it collected in the lowest

part of the abdomen and did not interfere with the formation of the adhesions. If it became excessive at any time it might be drawn off again; and this, as shown by the history of the cases which recovered, might require to be done many times in the first few months, until the anastomotic channels had enlarged sufficiently. Ascites was a late and a very serious symptom in cirrhosis, aggravating all the rest and hastening the course of the disease. If, therefore, it was not complicated by diseases of other organs, and if the accumulated fluid did not quickly disappear under the influence of iodide of potassium, it seemed more rational to try to establish an efficient collateral circulation without further delay by an operation which, under such conditions, was not attended by any grave degree of danger, than to allow the patient to drift on in a state of perpetually increasing misery, relieved now and then by tapping, until, in the vast majority of cases, his strength sunk so low that it was too late to do anything more than to watch the progress of the disease.—Dr. CAMPBELL THOMSON referred to a paper on this subject which he had read last session before another society in which he had drawn a distinction between the cases in which the ascites was directly due to the cirrhosis of the liver and those in which it was caused by peritonitis resulting from the cirrhosis. The latter were the cases in which operation was likely to prove beneficial, as proved by post-mortem investigations. The former class usually proved rapidly fatal. Recovery, when it took place, was presumably due to obliteration of the peritoneal cavity by the formation of adhesions, just as pleurisy was cured by the adhesion of the layers of the pleura.—Dr. A. E. SANSON did not think that clinically it was possible to differentiate between the cases of pure cirrhosis and those associated with peritonitis. Cirrhosis was not a simple condition; on the contrary, it was a very complex thing, and he was not disposed to accept the previous speaker's conclusions in regard to the cases which recovered and those which did not. Therapeutically it was necessary to modify the balance of circulation and he thought that surgical measures constituted a better way of effecting this than the old-fashioned plan of tapping with copious diaphoresis.—Dr. NORMAN DALTON agreed with Mr. Mansell Moullin that a great deal depended upon the condition of the other organs. Certainly if there was marked oedema of the feet the results were not likely to be as good as when there was only ascites. He thought that the higher the incision was made the better in order to guard against the occurrence of ventral hernia which so often proved fatal later.—Mr. MANSELL MOULLIN, in reply, agreed with the last speaker in respect of the best site for the incision. He had operated after one or two tapplings—i.e., somewhat early in the history of the ascites.

**NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.**—The annual meeting of this society, followed by the first ordinary meeting of the session, was held in the Library of the Royal Infirmary, Newcastle-upon-Tyne, on Oct. 10th, Dr. Robert Smith, the President, being in the chair.—The following officers were elected for the ensuing year:—President: Dr. Robert Smith. Vice-Presidents: Mr. J. Rutherford Morison, Dr. R. S. Peart, Dr. W. Gowan, and Dr. J. Adamson. Honorary secretaries: Dr. T. Beattie and Dr. A. M. Martin. Committee: Dr. D. Drummond, Dr. G. H. Hume, Dr. J. Limont, Dr. J. Murphy, Dr. James Drummond, Dr. R. A. Bolam, Dr. I. G. Modlin, Dr. H. B. Angus, and Dr. R. P. R. Lyle.—The following gentlemen were elected members of the society: Mr. R. Stuart (Durham), Mr. P. Campbell Smith (Middleton Hall), Dr. W. G. Thompson (Sunderland), and Dr. H. H. Gourley (Gosforth).—Dr. V. Rutherford showed cases of Rodent Ulcer and of Lupus treated by X Rays. Case 1 was that of a man, aged 57 years, who had been the subject of rodent ulcer at the inner canthus for seven years. His treatment had amounted to 45 exposures, each of a quarter of an hour's duration. The result was a soft and soundly-healed cicatrix. The second case was that of a woman, aged 71 years, who had been the subject of extensive lupus of doubtful origin, probably specific, and who was now almost cured after 30 exposures. In Case 3 the patient was a woman, aged 50 years, suffering from rodent ulcer of the upper lip. She was improving after 15 exposures.—The President, Mr. G. Foggin, Dr. G. H. Hume, Mr. Morison, Dr. J. B. Wardale, and Dr. A. S. Percival took part in the subsequent discussion, which elicited the following points. The normal tissues around the

part exposed were protected by tinfoil. Dr. Foggin suggested the action as being chemical and caustic, referring to the action of blue rays as an analogy. Dr. Hume asked if there was any probability of this treatment being similarly effective in ulcerating internal growths. Dr. Percival suggested that the active agent might be the high frequency current which permeated along with the x-rays and to the vibrations of which no normal cell synchronised, it being therefore harmless to them and yet capable of killing certain organisms.—Dr. Beattie and Dr. Bolam showed cases of Diffuse Specific Aortitis; Primary Aortic Regurgitation.—Mr. W. G. Richardson brought forward a patient in whom Resection of Gut for Strangulated Hernia had been performed.—Dr. Martin showed (1) a Patent Meckel's Diverticulum (this specimen was removed from a child, aged three months); and (2) a man, aged 54 years, who exhibited a very extensive Nævus involving the lower lip, the cheek, the tongue, and the left faucial pillar and extending into the neck. The condition had existed since birth and it was considered too extensive to interfere with.—Mr. Morison brought forward Two Complicated Cases of Intussusception. The first was that of a miner, aged 62 years, who four months previously had severe colicky pains. The spasms came on several times a day, but sometimes a week elapsed between the attacks, which were accompanied by noisy rumblings and great constipation. The abdomen became swollen, especially in the right iliac fossa. During the last months the pains had been very severe and they had been accompanied by vomiting and sweating. The patient had lost weight and was very weak. On admission into hospital he was found to be an emaciated old man with a distended abdomen and presented a rounded mass in the caecal region and a harder mass above and to the right of the umbilicus. Operation revealed a large ileo-caecal intussusception extending as far as the centre of the transverse colon. After reduction a mass was felt in the lower end of the ileum about three inches from the caecum. The involved portion of bowel was excised and the ends were united by direct suture. The patient made a good recovery. The specimen showed the condition to be a large polypus of the ileum which had produced the intussusception. Microscopically it proved to be a myxoma. In the second case a male, aged five years, had been 24 hours before admission suddenly seized with acute abdominal pain and vomiting. The pain was paroxysmal; blood was passed per rectum. The boy was in good condition and presented a sausage-shaped swelling in the left iliac region. On operation the intussusception of the lower ileum was found after reduction to have been produced by an inverted Meckel's diverticulum. The diverticulum was removed and the boy made a good recovery. The specimen showed the Meckel's diverticulum as it was removed turned inside out.

**FOLKESTONE MEDICAL SOCIETY.**—A meeting of this society was held on Oct. 4th at the Queen's Hotel by invitation of Mr. H. A. Powell.—Dr. J. E. G. Calverley and Dr. A. Gordon Wilson were elected members of the society. The report of the Library Committee was received and adopted.—Dr. T. Eastes read a paper on Clinical Errors. He drew attention to various difficulties and mistakes which he had met with in practice, such as cases of polypus uteri mistaken for pregnancy, distended bladder where the normal amount of urine appeared to have been passed, pancreatic cysts simulating abscess in the abdominal wall, and pregnancy diagnosed where it did not exist and being unexpectedly discovered where it had not been diagnosed. He insisted upon the importance of bearing in mind the possibility of pregnancy in all kinds of obscure abdominal swellings, especially when any abdominal section was contemplated, as otherwise serious consequences might arise. Various kinds of injuries were mentioned, especially those about the hip and shoulder, as being sources of many errors and difficulties. Two cases of impacted fracture of the neck of the femur which had become loosened after two or three days served to illustrate the importance of not speaking too positively about the prognosis or diagnosis in such cases until a certain interval had elapsed. Stress was laid upon the use of Bryant's line for diagnosis. The help given by x-ray shadow photography was mentioned, also the danger of the public being misled by the same. The difficulties met with in cases of rash were recognised, also the uncertainty of diagnosis at the commencement of a case of enteric fever. Laryngismus stridulus and whooping cough had been confused. The dangers arising from

the similarity of diphtheria and follicular tonsillitis and the help derived from bacteriology were considered. Some cases of poisoning from drugs were described, the list including morphia, digitalis, Easton's syrup, carbolic acid, phosphorus, belladonna (severe symptoms from the use of a plaster seven and a half inches by four inches for a few hours), cocaine, turpentine, aconite, iodoform, copaiba, bromides, salicin, thyroid extract, and acetate of lead. In operations incision of the tumour was strongly advised in breast cases where there was any possible doubt as to the malignancy of the swelling. Two cases of injury to the uterus during forcible dilatation were mentioned, but in neither did any bad result seem to follow. Dr. Eastes concluded by saying that tales against another medical man's reputation coming from a patient who had just left that gentleman should be discredited. Probably the patient was still in that medical man's debt and had been requested to settle up and instead had called in a fresh medical attendant, to do the same again later.

**LEICESTER MEDICAL SOCIETY.**—The half-yearly business meeting of this society was held on Oct. 1st, Mr. H. J. Blakesley, the President, being in the chair. The President-elect was conducted to the chair by Mr. Blakesley.—A vote of thanks to the retiring honorary secretaries having been passed, Dr. Astley V. Clarke and Dr. R. W. W. Henry were elected to fill their places, the latter gentleman being in place of Mr. N. C. Ridley who resigned office. The following, with the officers, were elected to the Council: Dr. J. Peacock and Dr. J. Hunter, with Mr. Ridley and Mr. C. D. Nuttall.—The following motions were carried in silence:—

That this society records with much regret the death of Dr. John Healdley Neale. His premature death at the age of 51 years is a great loss to the society and the medical profession of Leicester.

That this society records with great regret the sudden death of Dr. Julius St. Thomas Clarke, who was engaged for 40 years in medical practice in the town. He was a member of the society for 38 years, and a former president. He was held in high esteem among a large circle, and his death is a great loss to the society and to the medical profession of the town.

An ordinary meeting of the society was held on Oct. 4th, Dr. F. W. Bennett (President) being in the chair and 21 members being present. Mr. J. S. Sloane was elected a member. Dr. Bennett read a paper on Medicine and Legislation, a Forecast. He divided the subject into two parts: (1) methods to improve the existing race, and (2) methods to safeguard the future race. In the first part he discussed (a) the effect of dust on the atmosphere and its influence in lessening the intensity of light; (b) the advantages to be derived from medical inspection in schools; and (c) the importance of legislation in preventing the spread of tuberculosis by expectoration. In the second part Dr. Bennett discussed the following points: (a) examples of hereditary influence in disease; (b) the frequency of deaf-mutism; (c) the hereditary influence in the congenital cases; (d) the danger of marriage of the deaf; (e) the amount of deafness among the families of the deaf; (f) the amount of nerve defects in these families; (g) the frequency of mental defects; and (h) the hereditary factor in mental disease. He advocated legislative changes to prevent (a) intermarriage of deaf-mutes; (b) intermarriage of hearing people who belonged to families having more than one deaf-mute; (c) marriage of confirmed epileptics; (d) marriage of confirmed drunkards; (e) marriage of those who had once been insane, provided the family history showed a marked taint; and (f) marriage of those who had been more than once insane.—A vote of thanks to the President was carried, on the motion of Dr. F. M. Pope, seconded by Mr. G. C. Franklin.

**PLAISTOW AND CANNING TOWN MEDICAL SOCIETY.**—A meeting of this society was held at the Public Hall on Oct. 4th, Dr. W. C. Taylor being in the chair.—Some questions of a medico-political nature having been discussed a few interesting cases were exhibited by members.—Mr. J. Jordan Harvey showed: (1) A case of Gummatous Ulcer of the Upper Lip in a middle-aged man simulating Epithelioma; (2) a case of Irritable Ulcer of the Leg in an old man; and (3) a case of Congenital Heart Disease with Cyanosis of the Extremities and Webbing of the Fingers and Toes.—Dr. E. Hay showed a case of Mitral Incompetence with Hypertrophy of the Heart in a boy aged four years.—Dr. Leonard G. Guthrie then read a paper on the Treatment of Hemiplegia, which is published in full at page 1035 of our present issue.—A discussion followed in which most of the members present

took part and several questions were put to the lecturer.—Dr. Guthrie, in reply, said that purely motor aphasia might in some cases be improved by instruction on the "oral" system as used for the deaf and dumb. The vocabulary of a patient suffering from "verbal amnesia" had been somewhat increased by making him repeat the names of things over and over again. He (Dr. Guthrie) knew of no methods of improving "word deafness" and "word blindness." He doubted whether digitalis and other drugs were of service in cases of localised œdema—massage and bandaging were more efficacious. Passive movements of the limbs should be employed from the first. Age and the nature of the primary disease were no disqualifications. Treatment of infantile hemiplegia did not differ from that of adults. Cases in which the limbs remained flaccid instead of spastic were generally functional in nature.—A hearty vote of thanks to Dr. Guthrie was then carried and the meeting adjourned.

**BRITISH ORTHOPÆDIC SOCIETY.**—A meeting of this society was held at the Royal Orthopædic Hospital on Oct. 12th.—Mr. H. A. Reeves, who was in the chair, showed: (1) A case of Congenital Absence of Both Fibulæ; (2) Skiagrams of a Similar Deformity in an infant, with Fusion of the Great Toe and the First, in relation to their Phalanges; (3) a Photograph and Skiagram of a case of a woman, aged 42 years, with Lateral Deviation Outwards of all the Fingers at the First Inter-phalangeal Joints (cause unknown); (4) a case of a girl, aged 14 years, with Extreme Valgus of Both Feet and Great Wasting of the Leg Muscles with Partial Dislocation of both Patellæ; and (5) Photographs of Contraction of all Fingers of Both Hands (like Dupuytren's) in an infant.—Mr. Noble Smith showed: (1) Photographs and Skiagrams of a Child, six years of age, with Great Attenuation of the Muscles and Bones of the Leg, with well-marked Anterior Curves; (2) Photographs and Skiagrams of a Rachitic Case, the patient being six years of age, with Peculiar Formation of the Lower Ends of the Femora; and (3) an Engraving of Carcinoma of the Spine secondary to Carcinoma of the Left Femur.—Mr. Muirhead Little read an interesting paper on the Treatment of Lateral Curvature of the Spine.—A very instructive discussion followed in which the following members took part: Mr. Reeves, Mr. C. B. Kestley, Dr. Percy Lewis, Mr. Noble Smith, and Mr. Chisholm Williams.

**BRITISH GYNÆCOLOGICAL SOCIETY.**—A meeting of this society was held on Oct. 10th, Dr. J. A. Mansell Moullin being in the chair.—Dr. F. A. Purcell showed a Cystic Sarcoma of the Right Ovary removed by Abdominal Cœliotomy from a single woman, aged 52 years. The specimen weighed eight pounds. Its circumference at its greatest diameter measured 26½ inches and at its least 18 inches. The patient had lost nothing since the menopause which had taken place six years previously. She had suffered considerable abdominal pain for some time before the swelling first became evident, five or six years before. The uterus, two and a half inches in length, was separate from the tumour. A considerable amount of ascitic fluid was present. The patient made an uninterrupted recovery.—Dr. H. Macnaughton-Jones read a paper entitled "Gynæcological Cases" which is published in full at p. 1031 of our present issue.—Dr. W. Travers read a short communication on a case of a Fibroid Tumour simulating Appendicitis and causing Intestinal Obstruction. The tumour was removed. Some months had elapsed since the operation and the patient now performed her duties without discomfort and any constipation was easily overcome.—A discussion took place upon Dr. Travers's communication and upon the specimens shown.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY.**—The first meeting of the forty-sixth session of this society was held at the Royal Kent Dispensary, Greenwich, on Oct. 4th, Dr. G. Herschell, Vice-President, being in the chair.—The treasurer's accounts and the annual report having been read and adopted and several new members having been elected the following were chosen as officers and council for the ensuing year:—President: Dr. Thomas C. Meggison. Vice-Presidents: Dr. Herschell and Dr. Robert E. Scholefield. Council: Mr. F. Septimus Barnett, Mr. Leonard A. Bidwell, Mr. Charles J. Heath, Mr. Arthur E. Joscelyne, Mr. William Henry Payne, Mr. Chisholm Williams, and Dr. H. Bowen Williams. Treasurer: Mr. John P. Purvis. Secretary: Dr. John P. Henry. Librarian: Dr. F. S. Toogood.—The following cases were then shown. Dr. Toogood: (1) A case of Syringomyelia; (2) a case of Paralysis Agitans; and (3) a case of Removal

of the Right Kidney for Hydronephrosis.—Dr. Scholefield: (1) A case of Lupus treated by the X Rays; (2) a case of Pigmented Symmetrical Dermatitis on Both Cheeks; and (3) a case of Cerebral Tumour.—Dr. Joscelyne: A case of Rupia with a Negative History of Syphilis.

**YORK MEDICAL SOCIETY.**—The inaugural meeting of the session of this society was held on Oct. 9th, when Dr. G. H. Savage of Guy's Hospital, London, delivered an address on the Influence of Surroundings in the Production of Mental Disorder before an audience of about 300 ladies and gentlemen. The address created the very greatest interest.—The annual dinner of the society took place the same evening, when 44 members and friends were present, including the Lord Mayor, the Dean of York, Dr. Savage, Colonel Fielden, Colonel Mapleton, R.A.M.C., Colonel Haynes, Professor Trevelyan, Mr. Lawford Knaggs, Dr. C. Powell White (Leeds), and Dr. A. C. F. Rabagliati (Bradford). Dr. J. H. Buchanan, J.P. (Thirsk), President of the society, occupied the chair. Dr. Bedford Pierce, ex-President, proposed the toast of the evening, "The Orator," which was humorously responded to by Dr. Savage.—The office-bearers of the society for the ensuing session have been recently elected as follows:—President: Dr. Buchanan. Honorary librarian: Dr. J. Ramsay. Honorary curator: Dr. D. S. Long. Honorary secretaries: Dr. Edmund M. Smith and Dr. G. A. Auden. Other members of the Council: Dr. Pierce, Mr. W. Draper, Mr. W. H. Jalland, Mr. H. C. Shann, and Mr. J. H. Gostling.

**CARDIFF MEDICAL SOCIETY.**—The opening meeting of this society was held at the society's rooms on Oct. 3rd, Dr. D. R. Paterson, the President, being in the chair.—The President showed a case of Cervical Pachymeningitis.—Mr. William Sheen showed a patient with Hypertrophy of one Side of the Head and Face in which all the structures—bones and soft parts—participated. Two large flaps of skin had been removed with considerable resulting improvement in the patient's appearance.—Mr. Sheen also showed a Kidney on which Nephrotomy had been performed, an abscess being opened. Subsequently the kidney was removed and a second abscess was found to be present in the cortex, in the wall of which tubercle bacilli were found.—The President read an address on "Some Defects in our Medico-Legal System."—On the motion of the President, seconded by Dr. T. Wallace, the society heartily congratulated its senior secretary, Mr. Lynn Thomas, on being made a Companion of the Bath as a reward for his services with the Welsh Hospital in South Africa.

**MANCHESTER MEDICAL SOCIETY.**—The opening meeting of this society was held on Oct. 2nd.—Professor A. H. Young, the President, gave an account of the Structure of the Ovum and described in detail the phenomena of the karyokinetic division of cells. The different phases were illustrated as they occurred in the equal division of the ovum which followed fertilisation and constituted the process of segmentation. They were also illustrated by the process of unequal division of the ovum which occurred during its maturation and resulted in the formation of the polar bodies. The phenomena observable during maturation, fertilisation, and segmentation were further illustrated, as they occurred in echinus esculentus, by a series of lantern slides for which Professor Young expressed his indebtedness to Dr. T. Bryce of Glasgow.

**HULL MEDICAL SOCIETY.**—The thirteenth annual meeting was held in the Library Room of the society on Oct. 11th, Mr. T. M. Evans, the President, being in the chair.—After some formal business had been transacted the meeting then proceeded to the election of office-bearers with the following result:—President: Mr. R. H. B. Nicholson. Vice-Presidents: Mr. T. M. Evans and Dr. Edward Harrison. Secretary: Dr. James MacNider. Librarian: Dr. Robert Grieve. Members of Council: Dr. Thomas Cameron, Dr. A. G. Francis, Dr. E. M. Hainworth, Mr. Edmund H. Howlett, Dr. David Lowson, Dr. Alfred Parkin, Dr. James L. Waters, and Dr. John Wyllie.

**WATER-SUPPLY OF BOVEY TRACEY.**—At the meeting of the Newton Abbot (Devon) Rural District Council held on Oct. 9th it was decided to apply to the Local Government Board for sanction to borrow £7000 for the purposes of a water-supply for Bovey Tracey. It is hoped that the new works will be ready for use next summer.

## Reviews and Notices of Books.

### *Diseases of the Thyroid Gland and their Surgical Treatment.*

By JAMES BERRY, B.S. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital, and Lecturer on Surgery at the London (Royal Free Hospital) School of Medicine for Women; Surgeon to the Alexandra Hospital for Hip Disease. London: J. & A. Churchill. 1901. 8vo, pp. 384. Price 14s.

ENLARGEMENT of the thyroid gland has from a very early date attracted the notice of physicians and others, and Greek and Latin writers frequently refer to this curious deformity, but it is only within comparatively recent years that the surgeon has been called upon to treat goitre with any frequency. It can hardly be said that England is a goitrous country, for there are many other parts of the world where affections of the thyroid gland are vastly more prevalent than in Great Britain. Yet when we consider the total population of these isles we need feel no surprise that the total number of cases in which the thyroid gland is diseased is very large, so that there is ample material in this country for the foundation of a very wide experience. The author of the work before us has devoted special attention to this subject for many years. In 1886 Mr. Berry was awarded the Jacksonian Prize by the Council of the Royal College of Surgeons of England for his essay on the Diseases of the Thyroid Gland, and in 1891 he delivered the Hunterian Lectures at the same institution on the same subject. On the essay and the lectures this work has been based, but the experience gained in the years which have intervened has naturally modified somewhat the views first expressed.

Many mistakes in reference to the thyroid gland have been made because of an insufficient acquaintance with the variations in the gland, which from their frequency may be called normal. The presence of accessory thyroids is very common, and their existence is of great importance from their connexion with the now almost discarded operation of complete thyroidectomy, a chapter on the anatomy of the gland is therefore of value. The anatomical relations of the gland and its vascular supply are of exceeding moment in operations on it, for the proximity of the recurrent laryngeal nerve and the large number and size of the thyroid vessels may easily lead to serious danger if the operator is not well acquainted with the anatomy of the normal gland.

But of all the diseases of the thyroid gland goitre is the most important. It is probable that to account for the origin of no other disease have so many theories been invented as for goitre, and yet it may be said that not one of them furnishes a satisfactory explanation. Most goitres in this country are probably of the endemic variety and it is to the investigation of the etiology of this form that chief attention has been directed. The author passes in review all the theories which have hitherto been brought forward. He shows that climate has little or nothing to do with the origin of the disease, for goitre is found both in the cold regions of Northern Siberia and in the territories of the Hudson's Bay Company on the one hand, and also in the Tropics on the other. The amount of rainfall and density of the atmosphere are equally unsatisfactory as etiological factors. The physical configuration of the country does not suffice to explain the origin of goitre; though it is true that the districts in which goitre prevails are nearly all hilly, yet many mountain ranges occur, such as those in Scotland, in which goitre is almost unknown. The want of air and of sunshine in some of the Swiss valleys has also been advanced as a cause, but many of the deep valleys of Norway are equally dark and gloomy and yet goitre is in that country very rarely seen. When we come to the geological structure of the soil we appear to be on surer ground, and Mr. Berry considers that

the true explanation of the association of goitre with hills is to be found, not in the configuration of the country, but in its geological structure. The nature of the underlying strata has an enormous influence on the nature of the mineral constituents of the drinking water of a district. The author gives us a very full account of the relation of goitrous districts to their geological structure, and as an outcome of his investigations he is inclined to believe that there is a real connexion between calcareous rocks and goitre. That the drinking-water of a district in which goitre occurs is responsible for the occurrence of the disease there seems but little doubt, for some epidemics of goitre have occurred in regiments which have been quartered in some particular village, and in some cases a village where goitre was formerly prevalent has changed its water-supply and goitre has ceased to occur. It may, then, be regarded as fairly proved that drinking-water is the channel by which the real cause of the disease invades the body. It becomes a much more difficult problem to determine what constituent in the water is responsible for the disease. Since the mere degree of hardness of the water appears to bear no relation to the frequency of goitre it is clear that calcium and magnesium salts do not give rise to the disease. Iron has been blamed, but on very little evidence. Mr. Berry quotes a series of experiments which he made some years ago. He gave to some guinea-pigs various salts of calcium, magnesium, potassium, sodium, and iron; yet though the experiments lasted nine months, no goitre was produced. Mr. Berry does not mention copper as a possible cause of the disease, although there seem to be several arguments in its favour. Of late micro-organisms have been credited with the power of causing goitre, but the proof is weak. Physical exertion appears to have little or nothing to do with the production of the disease, and heredity is at least as doubtful, though, as in the case of many other diseases, goitre occurs in families because all the members of the family are exposed to the same cause.

Of all the symptoms produced by an enlarged thyroid gland the most common and important is certainly dyspnoea, and this is produced by direct pressure on the trachea, for, as Mr. Berry points out, the rarity of dysphonia is clear evidence that the dyspnoea is not produced by pressure on the recurrent laryngeal nerves. A table is given containing notes of 34 cases in which fatal asphyxia was caused by pressure of a goitre, and from this table it is seen that although goitre is much more common in women than in men fatal dyspnoea occurred equally frequently in both sexes. A further important point deduced from this table is that in most of the cases the patients were young adults under 20 years of age—in fact, only seven were over that age. Further, unilateral goitres do not often cause fatal dyspnoea, and some of the most dangerous tumours are those which lie behind the sternum.

Naturally the most important portion of the book is devoted to a consideration of the treatment of goitre. For simple cases in which no operation is required the author advises that the patient should, if possible, remove to a district where the disease is not prevalent. The water suspected of causing the goitre should be filtered and boiled before being drunk, and if the patient is young and the goitre is small much benefit may be derived from the adoption of these measures. Of all internal remedies iodine and its preparations hold the first place, and in this connexion it is interesting to remember that nearly 2000 years ago burnt sponge, which contains iodine, was employed for goitre. Mr. Berry prescribes for ordinary cases of parenchymatous goitre five minims of tincture of iodine with four or five grains of iodide of potassium, the doses being gradually increased until the patient is taking three or four times as much. If the iodine in full doses does not produce a marked diminution in the size of the

gland in two or three weeks the author does not think it likely that it will do any good. If iodism is produced or the digestion is upset the administration of iodine should be diminished or stopped. With regard to local applications, Mr. Berry has not met with much success with the application of iodine. Tapping and injection of a goitre are condemned by the author who tells us that he considers that the advantages are incommensurate with the risks. Ligature of the thyroid arteries and exothyropexy do not commend themselves to Mr. Berry. As to division of the isthmus we are told that it is an operation not to be recommended except, perhaps, in certain exceptional cases. The two chief operations which are required in goitre are extirpation of a part of the thyroid and enucleation of a tumour from the interior of the gland. In the great majority of cases partial extirpation is the operation performed and the whole procedure is very carefully described and given in great detail. Mr. Berry tells us that if there is little or no dyspnoea or stridor there can be no objection to the administration of a general anæsthetic, but if there is any probability that serious dyspnoea may occur during the course of the operation then it is better to dispense with a general anæsthetic and to do the operation under cocaine or eucaïne. A general anæsthetic is especially dangerous if severe dyspnoea is present at the time of operation, for under such circumstances sudden death has occurred even before the operation has commenced. We need not follow the author through the whole operation; he discusses fully the various steps, and the description shows that it is written by one who knows his subject well.

An interesting chapter is added by Mr. Berry on the Results of Operations; and here it is shown that before 1851 the mortality was 31 per cent., from 1851 to 1876 it was 20 per cent., and from 1877 to 1882 it was 14.6 per cent. The mortality at present is certainly under 3 per cent., and in skilled hands it is probably less than 1 per cent. In Mr. Berry's last 80 cases there has been no death or serious complication of any kind. An appendix gives notes of 100 consecutive cases of removal of goitre by operation performed by the author since February, 1894. The book contains more than 100 illustrations, the majority of which represent patients before and after operation.

We may conclude by expressing the opinion that the book is one of the most important works in English on the subject with which it deals; it is clear, exact, and concise, and for many years it will be read and appreciated as a valuable account of the surgery of the thyroid gland.

*Handbook of Physiology.* By W. D. HALLIBURTON, M.D. Lond., F.R.S., Professor of Physiology, King's College, London. Fourth Edition, being the Seventeenth Edition of Kirkes' Physiology. With upwards of 680 Illustrations, including some Coloured Plates. London: John Murray. 1901. 8vo. Pp. 888. Price 14s.

THE frequency with which this work has been re-edited is sufficient evidence of its adaptation to the wants of the student. Originally founded on the lectures of Sir James Paget at St. Bartholomew's Hospital, delivered in 1843 and succeeding years, by Dr. Kirkes, it at once took a prominent place amongst the, at that time, rare works on physiology. Its only competitor was the excellent manual of Dr. Carpenter. Both works, by the introduction of histological details, then quite a novel feature, attracted attention and they became the recognised text-books of the schools. There was, indeed, a treatise of wider scope than either of these—Dr. Baly's translation of Müller's Physiology—but it was too profound for the majority of students and was, we imagine, consulted by teachers rather than by the taught. Those who had the privilege of listening to Sir James Paget's lectures could read his

language in many pages of the "Handbook" though they could not feel the charm of his delivery or experience the pleasure of listening to his exposition of facts and theories that were not to be found in any book published in English at that time. After several editions had been published by Dr. Kirkes the task of revising it and bringing it up to date was successfully undertaken by the late Mr. Marrant Baker and by Dr. Vincent Harris. A year or two ago, the demand for the work being still considerable, Mr. Murray wisely submitted it to the consideration of Professor W. D. Halliburton to determine whether it could be made a reflex of the actual condition of physiology. Professor Halliburton undertook the task and by striking out much that had become effete and by adding still more rendered necessary by the progress of physiology produced one of the best manuals for the student which we possess. So many and so considerable have been the alterations made by Professor Halliburton in the work that very little of the original now remains, and Mr. Murray in a publisher's note prefixed to the text states that in consequence of its high reputation and wide popularity he has determined to drop the time-honoured name of "Kirkes" and to substitute for it that of the real author of the volume, Professor Halliburton. Mr. Murray incidentally notices that a pirated edition has been for some years past in circulation in the United States for the contents of which he does not feel himself or the author responsible. Professor Halliburton states in his preface that he has once more subjected the book to a thorough revision whilst trying to keep in mind that the book is a student's text-book and that consequently unnecessary detail was to be avoided. New sections have been introduced on the significance of Nissl's granules, on Waller's work on the Electrical Currents of the Eyeball, on Cannon's researches in connexion with Stomach Movements, and on Waymouth Reid's Investigation of the Processes of Absorption. Many other sections have been extended and modified, though the size of the work has not been enlarged owing to the elision of antiquated matter. Several new woodcuts have been introduced, but some of the old ones want renovation, notably the chromo-lithograph representing blood and other spectra, which is very coarse, and Figs. 146, 268, and 344. These and several others contrast unfavourably with the beautiful drawings in various French and German treatises. Considering the importance of the sympathetic system of nerves a section might be added to bring the facts distributed through the volume to a focus. The sections dealing with the Chemistry of the Body are, as might be expected, both full and accurate. The book is an eminently trustworthy one and will prove, whether read alone or in conjunction with others, a valuable foundation for, and introduction to, the large treatises on physiology.

*Die Behandlung der Entzündlichen Erkrankungen der Gebärmutter-Adnexe mit dem galvanischen und dem faradischen Strome (The Treatment of Inflammatory Affections of the Uterine Appendages with the Galvanic and Faradaic Current).* By Dr. JOHANN KALABIN. With 3 Illustrations in the text. Jena: Gustav Fischer. 1901. 8vo. Pp. 230. Price 6 marks.

THE author has treated a considerable number of cases of salpingo-oöphoritis, both simple and gonorrhœal, and chronic inflammation of the ovaries by the galvanic and faradaic currents. He has embodied his own results as well as the results of his colleagues and those recorded by others in this *brochure*. Personally, in cases of salpingo-oöphoritis he employs the galvanic current. The positive electrode is placed in the vaginal fornix corresponding to the diseased tube, or in either fornix alternately, and the negative electrode, the clay one of Apostoli, upon the abdomen. The strength of the current varies from 10 to 50 milliampères, and the number of the sittings, which

Last from seven to 15 minutes, are from 15 to 30. The patient, after a rest of about a quarter of an hour, is allowed to return home and to resume her normal occupations. The author combines with this treatment the use of daily hot vaginal douches. If necessary the patient returns at the end of six months and if it be required is subjected to a further course of from five to 15 sittings. In the treatment of chronic inflammation of the ovary Dr. Kalabin uses the faradaic current. The one electrode is placed in the vaginal fornix and the other, a copper plate covered with flannel, upon the abdomen. As the result of his own experiences and of the results obtained by others the author comes to the following conclusions. The treatment of salpingitis and salpingo-oöphoritis with the constant current often leads to a complete or almost complete cure. The presence of a pyosalpinx contraindicates such treatment. Of 24 cases of pyosalpinx treated in this way in five the condition was rendered worse and in one death ensued. The bleeding accompanying salpingo-oöphoritis tends to cease as a result of vaginal galvanisation with a current of 30 milliamperes. The cessation of the bleeding does not depend upon cauterisation of the mucous membrane of the uterus. Salpingitis and salpingo-oöphoritis complicated by fibromyomata of the uterus or broad ligament should not be submitted to electrical treatment. In many cases of oöphoritis, more than half of the cases collected, the use of the galvanic or faradaic current led to complete recovery. The use of the constant current for the treatment of salpingitis and salpingo-oöphoritis due to the gonococcus leads in many cases (11 of the 42 recorded) to a good result. The exact part played by the electrical treatment in these cases is difficult to determine. We are, however, even yet only on the threshold of our knowledge with regard to the use of electricity in these and many similar conditions, and the author's results are therefore of considerable interest.

*The Mental Functions of the Brain.* By BERNARD HOLLÄNDER, M.D. Freiburg in Baden, M.R.C.S. Eng., L.R.C.P. Lond. London: Grant Richards. 1901. Royal 8vo. Pp. 512, with several Plates. Price 21s. net.

IN this work an attempt is made by the author in the direction of the revival of phrenology and the "clearing up of the mystery of the fundamental psychical functions and their localisation in the brain." Dr. Holländer, moreover, claims that it is the "first work on the subject since the dawn of modern scientific research," and seeks to base his views on scientific data, clinical, pathological, and comparative. The work is thus a pretentious one and its claims are of an exceptional character.

After a discursive sketch of the present state of mental science the author proceeds to deal with the pathology of melancholia. Starting from observations attributed to Jensen and Tigges that the frontal lobes of the brain are not affected by loss of weight in melancholia, in contrast to general paralysis, a localisation is sought for melancholia in the parietal lobe, or, to be more exact, in the angular and supra-marginal gyri. Indeed, this "discovery" is said to have been foreshadowed by Gall, the founder of phrenology, in the beginning of the nineteenth century. A number of cases culled from various sources and of varying degrees of value are quoted to support this conclusion, and in some of these the co-existence of word-blindness is noted. Many of the facts quoted are, however, open to other interpretations, and the author's conclusions at the end of the chapter are by no means established, especially his thesis that the "emotion of fear" is located in these gyri. In the following chapter the localisation of violent mania regarded as a morbid form of the emotion of anger is attempted. Gall's description of the brains of homicides is acknowledged as the basis

for this localisation, and several post-mortem records are cited. The following is a typical instance of the author's method of stating facts and deducing conclusions. "Male, aged 19, admitted into the asylum suffering from *epileptic mania*. He was described as very violent before and after the attack. On admission he was found to be a muscular youth. . . . Mentally he was irritable and excitable, took offence at trifles. Post mortem.—*Tumour found at the base of the brain*" in the left lenticular nucleus. This case is cited as one of the "proofs" that *mania furiosa* is located in the temporal lobe. A similar loose handling of data is observable throughout the book and not only detracts greatly from its value but weakens our belief in the soundness of the author's judgment generally. A similar verdict must be recorded of the connexion alleged by the author to exist between irascible mania and otorrhoea with earache. So, too, much of the neuro-pathology quoted by the writer is antique and obsolete. For instance, the old and abandoned view that epilepsy is due to sclerosis of the cornu ammonis and to asymmetrical enlargement of the lateral ventricle is made the foundation for further localisation, and the conclusions (nine in number) recorded on pages 181 and 182 are rendered doubtful. Delusional insanity with ideas of persecution is next located in the posterior temporal region, and kleptomania in the anterior temporal region in accordance with an observation of Gall that incorrigible thieves had a prominence in the corresponding part of the skull. When the subject of aphasia in its various forms is touched upon the clinical material is more satisfactory and an attempt is made with great dexterity to read into the conclusions of clinical neurology a phrenological theory. Among other curiosities we find "veneration" localised at the crown of the head (the site of the anterior fontanelle), while sexual desire is located in the lateral lobes of the cerebellum.

#### LIBRARY TABLE.

*Atlas and Epitome of Labour and Operative Obstetrics.* By Dr. OSKAR SCHAEFFER. Authorised translation from the fifth German revised edition. Edited by J. CLIFTON EDGAR, M.D. With 14 Lithographic Plates in colours and 139 other Illustrations. Pp. 110 and plates. London and Philadelphia: W. B. Saunders and Co. 1901. Price 9s. net.—*Anatomical Atlas of Obstetrics.* By Dr. OSKAR SCHAEFFER. Authorised translation by J. CLIFTON EDGAR, M.D. With 122 Figures in 56 Lithographic Plates, and 38 other Illustrations. Pp. 315. London and Philadelphia: W. B. Saunders and Co. 1901. Price 13s. net.—Dr. Clifton Edgar has made an authorised translation from the fifth revised German edition of the *Atlas and Epitome of Labor* and from the second revised German edition of the *Anatomical Atlas of Obstetrics*. The two German editions were noticed by us in THE LANCET of Oct. 28th, 1899 (p. 1173), and June 23rd, 1900 (p. 1807). The translator has made no additions to the text and has allowed the classification of presentations, positions, and obstetric operations to stand as in the original; in all statements of the French weights and measures, however, the English equivalents have been given. As we have already said, the amount of information contained in these two volumes is considerable, and for the English student or practitioner who wishes to become familiar with current German views and teaching in obstetric medicine the translations will prove of service. The translator appears to have done his work well and many of the figures are of value and well reproduced.

*Banks and their Customers: a Practical Guide for all who keep Banking Accounts, from the Customer's Point of View.* By HENRY WARREN. Fifth edition. London: Effingham Wilson, Royal Exchange, E.C. 1901. Pp. 77. Price 1s.—The author writes as one who is evidently "behind the scenes," and it is somewhat appalling to

the majority of us, who look upon our bankers as highly respectable old gentlemen and entirely above suspicion, to learn that they are all more or less opportunist thieves. We trust the author's views are exaggerated in this respect. Mr. Warren also does not hesitate to give utterance to his opinion that the reason why bank clerks do not "oftener make a bolt with the cash or indulge in extensive forgeries" is that "they have not got the pluck." Alas for the boasted civilisation of the twentieth century and the teaching of the various Christian bodies that the reason why a man does not rob his employers is not the restraining influence of duty or of religion, but want of pluck! We are the better for the fewer exhibitions of such pluck. Apart from this, the book contains some very useful information.

#### JOURNALS AND MAGAZINES.

*Revue d'Hygiène et de Police Sanitaire.* Vol. XXI. No. 9, Sept. 20th, 1901. Paris: Masson et Cie.—In this number Professor Fournier asks the somewhat difficult question whether or not the students of the higher classes in schools should be initiated into the dangers of venereal diseases. Professor Fournier answers the question in the affirmative and he points out that out of 10,000 cases of syphilis 822, or 8.22 per cent., contracted the disease before the twentieth year—i.e., from 14 to 19 years of age. Similarly he shows, when dealing with severe tertiary manifestations, what a large proportion of such cases contracted their primary infection before the twentieth year. Professor Fournier holds the view that boys who are budding into manhood should be told the dangers of venereal disease and warned how widely distributed such diseases are among women practising either open or clandestine prostitution. There are two other original communications in this number: one by Dr. Berthier upon Rational Boots and the other by Dr. Raynaud on the International Sanitary Council of Morocco; but the greater part of the volume is taken up with the doings of the British Congress on Tuberculosis.

*Children's Ailments and How to Treat Them.*—The Home Series. Edited by FLORENCE WHITE. London: Grant Richards. Pp. 100. Price 2d.—This little book is as excellent as its predecessor, "Home Nursing," which we had occasion to notice very favourably. Intended for the guidance especially of those to whom medical advice may be difficult of access, through pecuniary or other reasons, the book gives sound practical directions in just those matters where an uninformed mother may work so much unintentional harm. Care and cleanliness in the feeding and general surroundings of infants, simplicity of life, abundance of fresh air and natural exercise are among the things the importance of which is demonstrated. Other chapters deal with common accidents and ailments of children in a simple and practical manner, likely to render the nurse and mother acquainted with these instructions less helpless if alone and a more useful assistant to the medical man than she would otherwise probably be.

**WEST OF ENGLAND EYE INFIRMARY, EXETER.**—The new West of England Eye Infirmary was formally opened by Lady Clinton on Oct. 4th. The plans of the building provide for a structure with wings on either side of the central block, but at present only the eastern and central blocks are complete, the remaining wing being delayed through want of funds. The sections completed have been erected at a cost of £18,000, towards which £12,000 have been received, so that £6000 have still to be raised. The institution is fitted up in the most approved manner and is lighted by electricity. Accommodation is provided for 50 in-patients; when the remaining wing is completed this number will be increased to 85. At present the new structure is connected by a covered way with the old infirmary, the second oldest eye infirmary in the kingdom, which will continue in use until the additional wing is ready.

## Analytical Records FROM THE LANCET LABORATORY.

### "PHOS. CO." BAKING POWDER.

(THE "PHOS. CO." MANUFACTURING COMPANY, LIMITED, 91A, CHEAPSIDE, LIVERPOOL.)

It is satisfactory that the Food and Drugs Act of 1899 includes baking powder as an article of food in its provisions, because injurious ingredients have been shown to be employed in baking powders, chiefly as substitutes for tartaric acid. Alum is well known as such an objectionable ingredient. So-called superphosphate or acid phosphate of lime has been used for a similar purpose. Providing that the superphosphate is pure and free from arsenic, which is not usually the case, little objection can be raised against its use considering the small quantity required for the efficient aeration of bread or pastry. Sulphate of lime, however, is an inevitable and considerable constituent of "superphosphate," and in some cases its presence in bread would be open to objection. But the quantity present in the loaf would be small. The baking powder under examination differs from most powders in containing an acid salt which by its interaction on carbonate of soda not only sets free carbonic acid gas but forms also a sodium salt which is a useful dietetic constituent. The powder on moistening effervesces briskly and its use in bread produces a loaf of excellent and uniform texture and of good colour. We could find no objectionable constituents in the powder. Its composition has been well thought out, so that it is not only useful for raising bread but increases its food value by augmenting the phosphatic constituents.

### LIQUEUR SCOTCH WHISKY.

(MARSHALL, McEWEN, AND CO., 146, ST. VINCENT-STREET, GLASGOW. LONDON OFFICE, 31, KING WILLIAM-STREET, E.C.)

This is an excellent and mature spirit, free from excessive extractives and without any appreciable degree of acidity. Analysis showed the following results: alcohol, by weight 39.80 per cent., by volume 47.13 per cent., equal to proof spirit 82.59 per cent.; extractives, 0.15 per cent.; acidity reckoned as acetic acid, 0.039 per cent.; and mineral matter, *nil*. The residue obtained on extraction by ether possessed the characteristic smell of a sherry cask. The flavour is smooth and malty, though somewhat sweet. The spirit gave no evidence of the presence of higher or injurious alcohols or of other raw products of which furfural is the type.

### MELLIN'S FOOD CHOCOLATE.

(MELLIN'S FOOD, LIMITED, STAFFORD-STREET, PECKHAM, LONDON, S.E.)

This chocolate contains an addition of the well-known Mellin's food and yields results on analysis in accordance with this description. It is of excellent flavour and evidently a chocolate of high quality is used for the purpose. Analysis showed, however, only a comparatively small proportion of proteid, the amount being 6.55 per cent. Carbohydrates were present in an easily digestible form and the mineral matter amounted to 2.62 per cent., consisting almost entirely of phosphates. The chocolate is a very agreeable food.

### COOYMAN'S LIQUEUR ADVOCAT.

(A. WEBSTER AND CO., LIMITED, 3A, BASINGHALL-AVENUE, COLEMAN-STREET, LONDON, E.C.)

This "liqueur" is made in Holland and, unlike most liqueurs, is a powerful restorative and food. It consists essentially of an emulsion of the yolk of egg with spirit, aromatics being added to give a pleasing flavour. Our analysis gave the following results: solid matters, 27.48 per cent.; mineral matter, 0.22 per cent.; water, 49.57 per cent.; alcohol, by weight 22.85 per cent., by volume 27.86 per cent., equal to proof spirit 48.82 per cent. The mineral matter contained, as might be expected, phosphates in abundance. Evidence of the presence of organic sulphur was distinctly gained. The preparation has an agreeable aromatic flavour and, considering its composition, is undoubtedly stimulant and restorative.

# THE LANCET.

LONDON: SATURDAY, OCTOBER 19, 1901.

## Hoch! Professor Virchow.

ON Saturday last an anniversary was celebrated in Berlin which has impressed the whole civilised world, and, in particular, has caused all those sections of thinking persons who take an interest in science to reflect on the possibilities for good that lie in the brain of an individual worker. For the proceedings in Berlin, as will be seen from our report of them, testify in a remarkable manner to the admiration which the whole scientific world has for the vast and far-reaching character of Professor VIRCHOW's pathological and anthropological work. Scientific men benefit their generation in different ways, just as men with powers of artistic achievement may do; but there is one rough difference very generally existent between the two classes. The artist has all life for his theme; the scientific man is, as a rule, a specialist in some department of life, which may be large or which may be small, but which is none the less a department. He does his work: probably this work overlaps the work of brother men of science who are applying themselves to the study of a second department of exact knowledge, and who in their turn overlap with their labours the labours being carried on in a third department. The world is especially fortunate if the outcome of such special endeavours can be made to fall under one great scheme; and of all the benefactors of civilisation the most practical is he who can not only detect the factors that are common to the separate results of individual endeavour, but who can systematise these results and interpret their true significance by the formulation of a general law. Such a man was DARWIN, such a man is LISTER, and such a man is VIRCHOW; and comparison can rightly be claimed for each of them with the poet or the painter. Professor VIRCHOW is one of the rare figures in the world's history of men who have been able to combine in their work the results of specialised endeavour with a poetically immense imagination. Just as great works of imagination—the really great picture, oratorio, or poem—deal with the elementary passions and appeal to us by senses that are common in greater or less degree to the whole world, so Professor VIRCHOW's pathological work has been large and simple. Extraordinary application and insight may have gone to its accomplishment, but its meaning is clear and its value undoubted. Fifty years ago he laid the foundations of modern pathology by beginning a series of investigations which terminated in the enunciation of the doctrine of *omnis cellula e cellula*. Before his work at Würzburg University there was no working theory that would really account for the commonest pathological processes. It was imagined that a formative but structureless blastema was thrown out between injured and separated surfaces, and that, for some reason or other, this blastema was obliging enough to become tendinous where the injury was of

tendon, muscular where it was of muscle, and so on. VIRCHOW perceived that the whole process had factors in common whatever the injury and whatever the tissue concerned; while his understanding refused to admit as satisfactory the theory of free-cell formation which amounted, in his opinion, to the doctrine of spontaneous generation. After much patient endeavour he demonstrated the fact that all living tissues were composed of cells and that the transforming and reparative processes which went on in those tissues were the results of changes in those cells.

He has himself put on record the circumstances in which his studies took the directions that have led to such great events, but those circumstances may well be repeated, especially as they bear out the view that only a man gifted with great powers of imagination could possibly have seen so far ahead, and so have been supported during his investigations by the expectation of important issues. It was towards the end of his academical studies, more than 50 years ago, that young VIRCHOW had to take up the work of assistant in the ophthalmic clinic of the Charité Hospital at Berlin.

"We had" (these are his words in the Huxley Lecture<sup>1</sup> delivered at Charing Cross Hospital in October, 1898) "severe cases of keratitis, but I saw in them no exudation. Numerous cataract operations were performed; the wounds were closed, but not by plastic exudation; this was absent from all corneal scars. Could this be explained by the circumstance that the cornea, apart from its circumference, is a non-vascular tissue? I then turned my attention to the non-vascular tissues; first to the articular cartilage, and behold, here also I found the greatest changes without the presence of exudation, or at any rate of plastic exudation. My experimental studies then extended to the walls of the larger arteries and then also in part to the veins, and they showed equally that they can undergo great changes without even a trace of exudation. Later investigations on endocarditis led to the same result, provided that parietal thrombi are not regarded as exudation. In all these cases and in every place we found changes in the tissue cells—active, such as multiplication of nuclei, or passive, such as fatty degeneration. Most of these processes were of the nature of proliferations."

It will be seen that VIRCHOW at once grasped the significance of his observations: he saw by the power of his imagination whither they would carry him. The actual phenomena lay before the eyes of all, yet this young house-surgeon was the first to whom their true meaning was revealed. He saw that the theory of a plastic exudation was arbitrary and erroneous. He saw, to use his words again,

"that there is no such thing as plastic exudation which is ever simply amorphous; the cells which have been found in it have not arisen there. It is proved in numberless places. The doctrine of the discontinuous origin of pathological new formations is set aside. Every such new formation presupposes tissue from which its cells arise, that is, its matrix. Pathology has been late in arriving at a knowledge of this correspondence, but I think it has acquired special value for biology in general. Proliferation is an active property of special cells but it cannot be performed by all cells alike. That in no way alters the fact that it can only be performed by cells. It is just as little a function of the entire organism, for this would then have to be unicellular. In this property lies the explanation of origin from a single egg, the wonderful process which comes to pass but once in the life of the animal. Once the tissues have arisen each cell of the tissue may, in respect of proliferation, be compared to an ovum; it brings forth a new progeny from which new tissue grows, this tissue bearing, as a rule, the stamp of its matrix; it is built on the maternal type."

<sup>1</sup> THE LANCET, Oct. 8th, 1898, p. 909.

As a result of Professor VIRCHOW's demonstration of these pathological views it follows that the pathologist of to-day can no more conceive of organised structures exhibiting vital phenomena, whether the simplest or the most complex, without reference to the cell as a unit than we can conceive of the sun apart from light and heat. The biologist, the pathologist, and the chemist, their labours all combined, cannot solve the whole problem of existence, but thanks to Professor VIRCHOW's labours—to his splendid imagination grafted upon his painstaking search for truth and his exact verification of detail—we can congratulate ourselves upon some progress. We can repeat with confidence another of his sayings, "that the future of medicine will be secured if the connexion between clinical practice and the facts of pathological anatomy and experimental pathology is maintained unbroken."

Professor VIRCHOW's career as a politician would have made him a notable citizen of the great German empire apart from all the work by which he has rendered his name internationally famous; but it is not our place to make more than a passing comment upon this phase of his full life. He has been called an ardent reformer, but his views were what might have been expected from a sound and enlightened man of science. He desired to see his country developed for the better, he worked for the gradual replacing of what was ill, for the regular elimination of faults, and for the no less regular introduction of improvements. He displayed in imperial and municipal politics the qualities of foresight and accuracy that had rendered him famous in science, and won golden opinions as an economist and a practical sanitarian. No true medical man can ever be a party politician—the label under which he votes can never more than partly describe his creed; and Professor VIRCHOW, while he was a Radical in conservative opinion, was ousted from his seat in the Reichstag for a Berlin constituency by the Social Democrats. As a true medical man he knew that complicated ills can hardly ever be dealt with by one drastic operation: they require all-round treatment. At the same time he knew that to tinker in this direction or in that, in the desire to deal with symptoms, and to neglect an exhaustive search for a common cause of the symptoms is almost certainly to condemn the patient to death. Hence his political life has been no bed of roses. Probably he could not go fast enough or far enough to please some, while his zeal for reform was too hot to suit others. He has lived to see the development of the German Empire from a congeries of isolated kingdoms, unable to see that their common good demanded a common policy and a common head, into a strongly welded union. He had stormy passages with the great architect of that Empire, Prince BISMARCK, and on all occasions he stuck to his guns. He was as a politician the true man of science, believing that all proceedings on a false theory must lead to disaster. Political quackery was abhorrent to him, and where he thought a system wrong, whatever the eminence of its supporters, he was bold to speak his mind. It is not to be wondered at that the career of such a man has inspired his scientific brethren with the desire to do him honour upon his eightieth birthday. We share that desire. HOCH! Professor VIRCHOW.

## The Reorganisation of the Royal Army Medical Corps.

THE report of the Committee on the Reorganisation of the Army Medical Services has, on the whole, met with a fierce fire of adverse criticism. It seems to be forgotten that that document is after all only a *report* embodying the recommendations of a committee, and it may be asked whether it is not somewhat premature to pronounce absolutely condemnatory judgment on a still immature scheme, about which there is yet so much to be learned? Might it not be well before entering upon a course threatening to arrest the growth and development of further efforts in this direction to wait until something more is known about the scheme and the intentions of the Government in regard to it?

There are two ways of dealing with the scheme at this stage of its career. One is to disregard any honest and well-intentioned attempt on the part of its framers to deal with a confessedly very difficult and complicated subject and to hail its advent by mercilessly setting about to find out all its flaws, actual or potential, thus threatening its existence *ab initio*. The other and more conciliatory method is to regard the aim and spirit of the scheme, as outlined, in a general, broad, and comprehensive manner, to credit its framers with honesty of endeavour and purpose if such be apparent on the face of it, and to defer the task of searching for all the blots and defects that might be discoverable in their proposals, until their exact effect and bearing are better known. By showing a disposition to consider frankly and favourably any *bonâ-fide* scheme of reorganisation a fair claim is set up that regard must be given to subsequent criticisms and objections. In the case of the long controversy that has been going on between the medical services and numerous Governments we have considered that it was in the interest of the medical profession as a whole and of the medical services in particular to take the latter course. It cannot be denied that the report of the Committee on the Reorganisation of the Army Medical Services, in addition to an increase in the pay of medical officers, contains some other good proposals and suggestions. If it contained nothing else than a suggestion as to the possible translation of the medical school from Netley to London and the provision of a military hospital in the metropolis, where medical officers would have unrivalled opportunities for seeing hospital work and for obtaining clinical instruction of the best and most varied kind, it would be a great step in the right direction and, as we believe, of great value to the medical service. We need not say that, having already advocated this measure, we quite concur in all that Sir WILLIAM MACCORMAC has recently said on the subject. As he pointed out, some institution is required similar to that of the Kaiser Wilhelm Institute of Berlin. It would have been easy enough to find a number of points in the report which lent themselves to criticism or about which misgivings would naturally arise, for some of them lie on the surface, but we thought that such criticism would follow naturally and smoothly upon detailed consideration of the scheme. As we have stated, the effect and working of some of

the recommendations must for a time partake of the nature of experiments, and these would probably lead to modifications, developments, and improvements being introduced for which we consider there is ample room left in the scheme. We have from the first regretted that Mr. BRODRICK did not nominate some army medical officer of high rank, experience, and recognised ability as a member of the Committee. It was unquestionably a grave omission. But in another direction the constitution of the Committee was carefully considered. It is plain that one of the great aims of Mr. BRODRICK and the Committee has been to bring the Army Medical Services into the closest relations with the medical profession in civil life. Several distinguished men in the civil branch of the profession, some of whom had had war experience in South Africa, and to all of whom the requirements of the profession might safely be entrusted, were nominated members, and took part in the proceedings, of the Committee. The report was signed by all the members, although two of their number have added exceptions—viz., Sir WILLIAM THOMSON and Professor ALEXANDER OGSTON.

We entertained from the first serious doubts as to the size and workability of the Advisory Board charged with its numerous functions, and we hold, as we have already stated, that the Director-General, who is to be its chairman, must have a seat on the Army Board. We have also indicated that the *chevaux de frise* of examinations and conditions set up by the report will have to be considerably modified; indeed, for our own part we should be prepared to see them removed, although some machinery must, of course, be provided for the efficacious testing of medical officers upon whom great responsibilities will devolve. In many other respects the recommendations of the Committee are susceptible of, and will assuredly have to undergo, alteration and improvement. Little or nothing is said in the report about service in India, presumably because nothing has yet been definitely settled between the Government in this country and that of India. There is, to our minds, no actual or implied finality about the report of the Committee. We are convinced that it is a scheme *honestly* put forward, and therefore we think that our professional brethren may well be invited to consider its merits as well as its shortcomings. Hastily to boycott it is to create an *impasse* at a most unfortunate juncture. Because the Army Medical Service has been badly treated in the past that is no reason why the scheme propounded by Mr. BRODRICK's Committee should not receive the attention which in many respects it deserves.

### Small-pox and Anti-vaccination.

HAWTHORNE wrote: "Nobody will use other people's experience, nor has any of his own till it is too late to use it." His conclusion might well have been founded upon study of the behaviour of those who now decry vaccination and who assume that its value as a prophylactic against small-pox has never been made the subject of proper inquiry. Mr. BERNARD SHAW, writing to the *Times*, tells us that vaccination has never been scientifically investigated because it has been assumed that the science involved is

the science of therapeutics, and of this most medical men, and almost all vaccinationist and anti-vaccinationist controversialists are so ignorant that they do not know that such a science exists and assume statistics to be a natural faculty of man, like English political public speaking. "Anybody can prove," he says, "by the statistical methods used by the disputants, and even by our Royal Commissioners, that typhus fever has been extirpated by the introduction of hair-brushing by machinery, or that the alarming increase of child-mortality from measles and adult mortality from cancer is due to the spread of teetotalism, to the use of the telephone, to vaccination, or any other contemporary phenomenon you please." He therefore proposes that the London University should be invited to undertake a purely statistical investigation of the question and to publish the result.

We have referred at length to Mr. SHAW's statement because it is illustrative of the carelessness which characterises the action of the would-be teachers of the public on a matter of such vital importance as their protection against small-pox. Mr. SHAW contends that only persons highly qualified in statistics deserve to be listened to on this subject and in the same letter he condemns in wholesale fashion the statistics which have hitherto been presented by those who have studied it. It is not easy to understand his position. He evidently feels no difficulty in claiming for himself that he is a competent judge of statistical validity while he denies to all others but highly qualified statisticians similar ability. With Mr. SHAW's desire that absolutely sound statistical methods should be employed in determining whether vaccination protects against small-pox we are entirely in sympathy; but with his view that he is a competent critic of the methods which have been used we equally disagree. We presume that he does not claim for himself that specialised statistical knowledge which he deems to be necessary, but if he does, it is obvious that he has not studied the abundant statistical evidence which exists and which proves conclusively the value of vaccination. No one with the least knowledge of this evidence could have written the sentence which we have quoted, for this evidence is of a sort altogether different from that which exists in respect of other diseases. The evidence is supplied by every epidemic of small-pox which prevails, and its effects upon two classes of persons living under circumstances which expose them to small-pox infection, the one the vaccinated class, the other the unvaccinated class. Comparison of the two classes may be made in respect of liability to attack, and among those who are attacked in respect of liability to death. The evidence is not limited to one town or to one country. It is a universal experience which is demonstrated in every community and every small-pox hospital at the times of epidemic.

The London School Board on Oct. 10th had before them figures based upon a comparison of the incidence of attack upon the vaccinated and the unvaccinated classes; and while Mr. GRAHAM WALLAS found reason for thinking that during the last 11 years in London small-pox had not manifested any greater tendency to attack the unvaccinated class Sir CHARLES ELLIOTT, using, he said, the same data, came to opposite conclusions. Mr. WALLAS, however, had assumed

that only 75 per cent. of the general population were vaccinated and he thought that this proportion was likely to be correct from the report as to the number of children who had escaped vaccination. It is here that he has fallen into error, for only in recent years has vaccination default been as large as stated, and continued default of this sort over a prolonged period would be required to justify Mr. WALLAS'S assumption. To apply the figures of the last few years to the population at all ages is a proceeding which Mr. SHAW would no doubt deplore. Sir CHARLES ELLIOTT was on safer ground. Referring to children only, and not to the population at all ages, he estimated the vaccinated proportion to be 70 per cent., and he allotted 348 cases of small-pox to the vaccinated and 899 cases to the unvaccinated, and further, dealing with deaths found that of 176 only two occurred "among properly vaccinated children and the remaining 174 among others." He does not appear to have stated the ages of the children to whom he was referring, but we may state generally that his figures will cause no surprise to those who are familiar with small-pox statistics.

We note, however, that Mr. WALLAS is not satisfied; nor, indeed, do we believe that if expert statisticians, satisfactory to Mr. SHAW, were to present to those who oppose vaccination the assurance of their satisfaction with the statistical evidence of its value that they would accept the assurance as deserving of their confidence. They would fulfil HAWTHORNE'S dictum. There are, however, large numbers of people who make no profession of knowledge of the subject; they follow, as indeed the greater number of us must follow in regard to much that concerns us in life, the teaching of others in whom they have confidence. It is here we would appeal to those who, as public men, can largely influence the action of this numerous class of the population. We ask them, before decrying vaccination in the public press or placing difficulties in the way of those whose duty it is to secure the protection of the public against small-pox, to be at pains to learn something of the subject with which they are dealing.

## Annotations.

"Ne quid nims."

### THE HOME OFFICE ARBITRATION ON LEAD POISONING.

IN accordance with the Factory Acts of 1891 and 1895 an arbitration is about to be held in regard to the desirability of imposing new rules in the china and earthenware manufactories. For many years now the danger of lead poisoning in this industry has been denounced and has been the subject of many investigations and reports. The manufacturers, however, object to the new rules and have appointed Mr. Fletcher Moulton, K.C., to represent them and to defend their interests before the arbitrators appointed by the Home Office. It is, of course, only fair that the employers should be able to state their views and to defend their interests, but it would not be fair if the other side of the question were not represented with equal ability and thoroughness. Here, however, a practical difficulty arises. The workpeople have equal right to state their case, but they have not equal means

of so doing. Arbitration is a very costly matter, and it is stated that the expenses of the solicitor for the workers will amount to about £250. It is true that Mr. W. S. Robson, K.C., has offered his services gratuitously if he is able to leave London at the time; but in the event of his absence a junior must be employed who must be a chemical expert. All this means money, which the manufacturers can easily afford, but which the workers do not possess. The trade unions concerned are only able to give £85, and some philanthropic persons who take an interest in labour and public health questions have subscribed further sums through the agency of the Women's Trades Union League, an organisation which has largely helped to awaken the attention of the House of Commons and of the public generally to the numerous cases of lead poisoning in the Potteries; but more help is wanted and we would point out that this is a question in which the public at large are interested as well as the workers engaged in this industry. The unscientific use of lead in the composition of glaze for enamelled saucepans and dishes used in cooking and in the storing of food has produced several accidents. The fat and acidity of food dissolve some of the lead in the glaze and thus there occur cases of plumbism in households that have no connexion with trades in which lead is employed. Therefore it is necessary that the umpire and arbitrator should have the case put fairly before them, and the attainment of the end in view must not be prevented by the fact that one side is better able to afford the expense of arbitration than is the other side.

### "THE CREATOR OF THE CELLULAR PATHOLOGY."

UNDER this heading Professor Hugo Ribbert of Marburg gives in the opening article of the *Deutsche Medicinische Wochenschrift* of Oct. 10th a summary of the development of the cellular pathology and of its position at the present day. The article is one of a series evoked by the occasion of Virchow's eightieth birthday which has been so enthusiastically celebrated in Germany. The study of the localisation of disease first took practical shape with Morgagni, whose great work, "*De Sedibus et Causis Morborum*," was published in 1761. It is owing to Virchow that the seats of disease are no longer localised in organs, as was done by Morgagni, but that the inquiry has been carried from organs to tissues and from tissues to cells. He originally held the view advanced by Schwann, that every cell was a new formation produced from an albuminous solution by a kind of crystallisation process; his opinions, however, gradually altered and in 1855 he taught that cells were formed only from pre-existing cells (*omnis cellula e cellula*), a doctrine which was the leading feature of his classical treatise "*Die Zellulärpathologie*," published in 1858. Virchow's discovery of the cells of the connective tissue formed the basis of his studies on parenchymatous inflammation in which the cells were first shown by him to be the seat of the disease. All subsequent investigations have been founded on these results, to-day no less than at the time of their first announcement, although in the course of time opinions may have undergone a change in some particulars. The knowledge of the importance of cellular changes in the explanation of morbid phenomena was only arrived at by degrees, and there are morbid conditions, such as nervous diseases, hysteria, and neurasthenia, to which even at the present time the doctrines of cellular pathology seem to be inapplicable. This, however, cannot be regarded as a failure of the theory, for it may be confidently expected that these symptoms will ultimately be traced to anomalies of the nerve cells, the pathological histology of which is only in the initial stage. If it is said that pyrexia cannot be explained according to the principles of cellular pathology it

may be replied that high temperatures and disorders of the heat-regulating faculty are probably dependent upon morbid conditions of certain cell groups of the central nervous system. Objections to the cellular pathology have for a long time been drawn from the phenomena presented by infectious diseases. But the exciting causes of infectious processes are only dangerous from the changes which they produce in the cells of the body, either directly or else indirectly by means of their toxins. Virchow himself has called special attention to the fact that in infection there is a struggle between cells and bacteria. Another view has been put forward to the effect that in infections changes occur in the blood, or, to be more precise, in its fluid constituents, which would be a return to the humoral pathology. But although the toxins actually produce certain changes in the substances contained in the blood in a state of solution, illness, nevertheless, is not manifested until the cells in some part or other have been affected. It is at present the almost universal belief that the bactericidal and antitoxic substances formed in the blood are produced through the instrumentality of cells. The cellular pathology is undoubtedly a well-established principle, and its illustrious originator has the satisfaction of knowing that for half a century it has been a reliable guide in many fields of medical inquiry.

#### "LOOKING BACK."

We have often commented upon the fact that the tendency nowadays amongst chemists engaged upon research is to become engrossed with the chemistry of the carbon compounds, probably because the materials are so abundant as to enable a never-ending list of new synthetic and very complex substances to be built up. This fascination has been very detrimental to the development of simpler chemistry, such as the chemistry of the inorganic elements. The ordinary facts of inorganic chemistry are accepted, but it often happens that in the light of modern inquiry the changes or actions or phenomena concerned are not so simple as was at first supposed. An excellent illustration of this will be seen in our "Looking Back" column to-day. As may there be found M. Döbereiner discovered the fact in 1823 that finely divided platinum possesses the power of determining the union of gases, but to this day the nature of the action is not precisely understood. All we know is that when a jet of hydrogen or other combustible gas is allowed to impinge upon finely divided platinum or platinum black in the presence of oxygen union of the gases results with such manifestation of heat that the platinum soon gets red hot. An apparatus generating hydrogen and provided with a cage of platinum was subsequently designed and known as the Döbereiner lamp. The principle has been applied, but with limited success, to the self-lighting of gas flames, obviating the use of matches or other means of igniting gas. We believe that the principle has been applied in connexion with the Welsbach light in particular. After a time, however, the platinum loses its property, perhaps by becoming damp or more probably by the effect of the destructive sulphur compounds in the coal-gas on the platinum. But the effect, as we now know, is not confined to platinum; other metals, such as palladium and gold, and even stones and glass according to Professor Tilden, exhibit the same property, although in a far lower degree, since they often require to be aided by a little heat. The explanation of the phenomenon is given by supposing that solid bodies in general have to a greater or less extent the property of condensing gases upon their surfaces and that this faculty is exhibited pre-eminently by certain of the non-oxidisable metals, such as platinum and gold. Why they possess this property we do not know. A warmed coil of platinum wire suspended over the wick of a spirit-lamp

will ultimately glow and amongst the products of partial combustion of the spirit is formaldehyde, one of the most powerful of modern antiseptics. Similarly a coil of platinum wire will glow in ether vapour, an irritating and incomplete product of combustion ensuing. As we have said, the exact nature of this interesting discovery recorded in our columns exactly 78 years ago is yet but ill understood and therefore it still leaves, in the words of this classic paragraph, "a new field for physical and chemical researches." It is interesting to add that it was six years after this discovery that Döbereiner pointed out that when families of closely-allied elements are examined they are commonly found to consist of three members. For example, in the case of chlorine, bromine, and iodine, or sulphur, selenium, and tellurium, or lithium, sodium, and potassium, the values of the atomic weights are so related that the middle term of the series is nearly the arithmetical mean of the two other terms. Thus the atomic weight of lithium is seven and that of potassium 39, and the mean of these figures is 23, the atomic weight of sodium. These observations were the foundation of the famous periodic law.

#### PSYCHICAL TROUBLES DUE TO A TUMOUR OF THE FRONTAL LOBE OF THE BRAIN.

In the *Revue Neurologique* of Sept. 15th Dr. Raymond Cestan and Dr. Paul Lejonne record an interesting case of a tumour involving the frontal lobe and attended with peculiar psychical disturbances. The frontal lobe has been hitherto regarded as a "silent" area of the brain in its anterior half—i.e., in the part in front of the Rolandic gyri—but the recent observations of Flechsig, von Bruns, and Höninger have cast doubt on that supposition. The following case throws some light on this obscure question. A woman, aged 33 years, was admitted into the Salpêtrière in August, 1900, suffering from right hemiplegia, complete blindness, and mental disturbance. She was free from neuropathic heredity, sober in habits, and free from syphilis and from convulsions during childhood. In October, 1899, she suffered from a violent frontal headache, persisting day and night, and of a gnawing character. Almost at the same time she developed epileptiform attacks with temporary loss of speech but without loss of consciousness. The symptoms became worse, she had attacks of vomiting, and gradually the fits tended to become generalised. In the beginning of 1900 she had a remission of these troubles, but optic neuritis accompanied by gradual failure of vision now succeeded, and in May, 1900, she was completely blind. The attacks of vomiting and the headaches had now quite disappeared. A third stage now followed as regards her disease, characterised by motor phenomena and intellectual disturbances. The motor symptoms consisted of a permanent right-sided hemiplegia and convulsions. Cutaneous sensibility was apparently normal and the stereognostic sense was unimpaired, though it was difficult to be certain on these points owing to the intellectual disorder present. The hemiplegia grew more marked, contraction of the right arm followed, and finally the sign of extension of the great toe on plantar stimulation (Babinski's reflex) made its appearance. She had on an average four or five slight epileptiform attacks and one violent seizure per month, but without loss of consciousness. The mental symptoms which appeared at the onset of her illness were a slight degree of intellectual apathy and torpor, which was probably associated with cerebral compression and which has been frequently observed in cranial neoplasms. But in May, 1900, a different mental condition appeared. She passed into a state of high spirits (euphoria), looking happy and smiling when spoken to, complaining no longer, and showing signs of good spirits and good appetite. Her intelligence, however, seemed a little blunted, and she laughed at almost

everything which was said to her. There were no hallucinations of sight or of hearing, no melancholic depression or maniacal excitement, and no moral perversion. She sat still most of the day, smiling and looking happy, exhibiting, however, little initiative or volition of her own (aboulia). Her memory for recent occurrences was not good; they did not seem to be properly retained in her memory as it now existed, and she failed to show the least recollection of what friends and relatives who now visited her had said to her. Her natural affection to them also seemed to be lost or replaced by indifference. Her habits were neat and clean and she was free from dementia. In April, 1901, a somnolent state succeeded the condition of euphoria, coma supervened, and she died in June. The necropsy revealed a large cystic tumour of the left frontal lobe of the size of an orange, filled with serous fluid and involving the posterior two-thirds of the prefrontal lobe and compressing the Rolandic area.

#### MISLEADING NAMES FOR GENERAL AND LOCAL ANÆSTHETICS.

It has been generally recognised that a great danger arises when powerful drugs are sold under factitious names, such names being not in fact the chemical designation of the poison contained in the compound. Of late this danger has been rendered greater by the introduction into the market of various substances of a most powerful and even lethal character which are vaunted as general or local anæsthetics under what are at best mere fancy names. In a recently issued French work we found several of such substances named, and there lies before us a catalogue of dental appliances in which are advertisements of other anæsthetics cloaked under registered names. As all such substances are puffed as being quite safe and in all respects ideal anæsthetics we think it time to put our readers upon their guard. It has been a mournful repetition of history that every anæsthetic has burst upon the horizon of practice as an "absolutely safe" body, only as time wore on to fall into the sphere of "dangerous" unless used with knowledge and skill. When we work with known substances, the physiological actions of which are recognised, we possess at least safe-guiding principles upon which to base our practice, but when we undertake to anæsthetise with a fancy nostrum we run a grave risk of summoning not Sleep but her twin sister, Death.

#### THE DUTIES OF A PUBLIC VACCINATOR.

A SUMMONS was applied for a few days ago at Marlborough-street Police-court for an alleged assault of a somewhat unusual nature. The advocate who made the application stated that a public vaccinator had visited a house and in the absence of the parents vaccinated two unvaccinated children whom he found there. The essence of the supposed offence was contained in the assertion that one of the children, aged 13 years, had protested that her parents and she herself objected to vaccination. Mr. Denman refused to grant a summons, pointing out that the children were liable to be vaccinated and the parents to be prosecuted in default, while if all that was alleged was proved there would only have been a mistake in duty committed without criminal intent. His decision clearly embodied sound sense and good law, for it is preposterous to suppose that the public vaccinator laid forcible hands upon a girl of 13 years of age and compelled her to undergo vaccination or that he terrified her into submission, and unless there was a likelihood of conditions such as these being proved it would have been waste of time to grant a summons. At the same time, we may congratulate the public vaccinator on having avoided a tedious and irritating ordeal. Not all magistrates have the strength of Mr. Denman, and excess of zeal may

place a public vaccinator who has erred from such a cause in an awkward predicament. Therefore it is advisable for those connected with the enforcement of the law rigidly to confine themselves to the duties which it imposes upon them. If the legislature does not sufficiently protect the unwise from small-pox, and if the unwise are unwilling to protect themselves and their offspring, no one is called upon to expose himself to the expense and worry of criminal proceedings in the fulfilment of what is at best a thankless task. We should mention that Dr. Purdie, in a letter which appears in the *Daily News* of Oct. 16th, states that the children in question never said or did anything to lead him to believe that their parents did not wish them to be vaccinated.

#### SMALL-POX IN LONDON.

DURING Tuesday, Oct. 15th, 10 fresh cases of small-pox were admitted to the hospitals of the Metropolitan Asylums Board, and during Wednesday, Oct. 16th, there were four fresh cases. At an inquest held on Oct. 15th into the circumstances attending the death of Annie Bowen, aged 12 years, the daughter of a coal-porter residing in Limehouse, some remarkable facts came to light. The mother, in giving evidence, said that the child came home on Oct. 10th from the Roman Catholic School in Copenhagen-place complaining of headache. On Oct. 13th she was seen to have a number of black and blue spots on her body. None of the witness's children had ever been vaccinated, neither had they been registered. Mr. Samuel Robert Dudley said that death was due to small-pox. He had seen five other of Mrs. Bowen's children, all of whom were suffering from small-pox. He informed the medical officer of health and within one hour all the children were removed. The eldest boy, whom he had also seen, would not await the visit of the medical officer of health. The jury, in returning a verdict of "Death from small-pox," commended Mr. Dudley for his promptness. It now remains for the fugitive boy to be caught. It was stated that he worked at a coal-merchant's and we trust that the merchant in question will insist upon his staff either being all vaccinated or leaving. The managers of the school should also give every facility for their scholars to be inspected; and this simple precaution, as the school is not a board school, will probably be carried out.

#### BERI-BERI AND ARSENICAL POISONING.

ABOUT a year ago, when the existence of an epidemic of peripheral neuritis in the North of England was discovered and the cause was ascertained to be chronic poisoning by arsenic in beer, Major Ronald Ross, who had seen several of the cases at Chester Infirmary, laid stress upon their marked similarity to tropical beri-beri, and at the recent meeting of the British Medical Association he again brought the possible relationship between beri-beri and arsenic to notice. If, as may be presumed, this question has since been locally investigated in regions where beri-beri is common, it would be interesting to know what positive or negative results have been obtained. Meanwhile, there is at least one suggestive case on record, that communicated by Major Ross and Dr. E. S. Reynolds to the *British Medical Journal* of Oct. 5th last. Here the patient, a Scottish lady and wife of a missionary, when living on the West Coast of Africa was attacked by peripheral neuritis, the symptoms of which were indistinguishable from beri-beri of the "paralytic" type. She had none of those symptoms unmistakably indicative of arsenic which characterised some of the later cases during the Manchester epidemic. While still suffering from the disease she returned to England and was admitted to the Royal Southern Hospital, Liverpool. Her hair was then examined by Dr. Dixon Mann who found in it considerable

quantities of arsenic, proving, to use his words, "that a considerable quantity of arsenic had been taken into the system of the patient, either by administration as medicine"—of which there is no affirmative evidence—"or in some other way." In this country we meet with beri-beri only at rare intervals, almost exclusively at our ports and among sailors. In most instances the sufferers are Asiatics, but occasionally at certain ports—Falmouth, for example—sailing vessels put in after long ocean voyages during which one or more members of a European crew have been attacked. It is noteworthy that in these cases rice, which has been suspected for good reasons to be associated with the disease in the East, has formed no part of the diet of the sufferers. It is, of course, possible that the peripheral neuritis which is the chief characteristic of the malady of these European sailors may not be due to the same cause as tropical beri-beri. But, however this may be, the few facts known about the ship-borne cases which come to this country suggest that the illness is to be connected in some way or other with diet rather than with an infective process, and it is important that here also arsenic should be kept in mind as a possible cause. We understand that the Royal Commission on Arsenical Poisoning last month invited the coöperation of the medical officers of health of certain selected ports in investigating the subject when opportunity offers, and this inquiry, together with the investigations which Dr. H. E. Durham and others are about to make on behalf of the London School of Tropical Medicine into endemic beri-beri on Christmas Island and elsewhere in the Pacific, may be expected at no distant date to throw some light upon this very interesting question.

#### RICH HEADS AND POOR DINNERS.

IN a passage of his "Confessions" descanting upon the nature of drunkenness De Quincey concludes that the exact condition indicated is a question of accuracy in terms. He was assured on medical authority that a man could be, and had been, drunk upon a beef-steak. This is largely true, for even solid food may produce at any rate great mental torpor. The comfort of a good dinner may have suggested a writer's theme, we doubt whether it ever promptly stirred his pen. It is the empty stomach that best suits a full head and ideas that flow out freely before retire with the entry of a substantial repast. Oliver Wendell Holmes, with that charming blend of wit and scientific knowledge that gave the distinction to his writings, has discoursed upon this very point. He talks of the "bulbous-headed fellows steaming as they write" and shows how to meet the demands of thought and imagination. The brain must have more than its share of the circulating blood. There must be no rival in the full liver or the actively digesting glands of the gastric mucous membrane. Do not eat heavily, then, if you are soon to think hard. Either your ideas or your dinner will be neglected and lie a sorry weight upon your head or your epigastrium. The poor half-starving poet is familiar to everyone. We may mitigate our pity by reflecting that in many cases he would have been no poet if he had not starved. Enough fuel to sustain the fire of life is necessary for work, but heap on the coal and you will deaden the overburdened flame. The great thinkers, the great workers in any direction but a purely physical one, have for the most part been abstemious men. If not naturally of small appetite they have exercised constant restraint, grudging from the play of higher functions every moment and every energy spent upon the animal activities of their nature. Habit soon helps the fine effort of such people, and it becomes natural for them to eat less, to drink less, and to sleep less than their fellows. Thus, in a long life of intellectual activity many scores of hours are utilised for the main purpose

which in the case of other men are squandered upon the dinner-table or in the mere nothingness of sleep or idling. Carlyle was justified in declaring a capacity for work to be the essence of genius. Whatever great man's life is read, no matter how brilliant his natural gifts, sooner or later he is found to have worked with unswerving constancy and imperturbable devotion. Others as gifted have left no mark; it was in the will and the power to work that the genius asserted itself. It is common to hear a man say, "So-and-so is a genius, if he worked he could do anything." Just because he does not work "So-and-so" must be denied the title. In the natural sciences, and professions such as medicine that depend upon them, the inevitableness of great work for great achievement is, perhaps, more obvious than in the service of art and literature. The artist and the writer of genius are gifted with inspirations falling to no man of mere talent, however hard he works. Yet even so the genius works to illustrate his inspiration, whether it is Raphael at his easel or Shakespeare at his desk, with a kind of frenzy of application and a continuous determination that are impossible to men not so endowed. Such labours of the will and of the brain demand at the time the whole energies of a human being. No lower member of the confederated body which is man must seek employment while the master parts are thus at work. So it is, then, that the little-eating worker blesses the world with fruits which the voluptuary and the *gourmet* may possibly enjoy at his well-fed ease, but can never hope in the least degree to emulate.

#### CHOLERA IN JAPAN.

VARIOUS epidemics attended with a great mortality are recorded in the Japanese annals, but no satisfactory data exist for the identification of the diseases concerned. In 1890 a committee was appointed by the Central Board of Health, Department for Home Affairs of the Imperial Japanese Government, to consider questions relating to the inspection of shipping and the sanitation of the ports open to foreign traders. The subject obviously involved a reference to previous experience of outbreaks of disease in Japanese seaports, and the committee arrived at the conclusion that the first positive knowledge of the prevalence of Asiatic cholera in Japan was in 1822. The second epidemic outbreak, according to Japanese accounts, was from 1858 to 1860; the third from 1877 to 1879; the fourth in 1881 and 1882; the fifth in 1885 and 1886; and the sixth in 1890 and 1891. The seventh and last epidemic, which continued from the beginning of 1895 to 1896, was undoubtedly a result of the war between Japan and China, and supplied material for an interesting report written by Dr. William F. Arnold of the United States Navy, at that time serving on the China and Japan station. This narrative was published in the annual report of the Surgeon-General of the United States Navy for the year 1897, and has just been reprinted by the author who, after an absence of some years, is once more in Japan. Statistics of cholera in the Japanese empire since 1877 have been published. From these it appears that in 1894 there were 546 cases with 314 deaths; in 1895 there were 53,999 cases with 38,500 deaths; and in 1896 there were 350 cases with about 150 deaths. The Japanese forces engaged in China suffered severely from cholera at the end of 1894 and beginning of 1895, but on the whole the incidence of the disease in the Japanese army and navy has been slight. In the navy during 1895 only 93 cases were recorded. No pains have been spared by the Japanese authorities in the repression of the various recent epidemics and great efforts were made to secure the coöperation of the public in preventive measures. In 1890 lectures, popular publications, magic-lantern exhibitions, effective illustrations, and handbills

were freely employed and the police regulations requiring cooked food to be protected from the access of house flies were vigorously enforced. In the city of Hiroshima a microscope was on view in a temple, and it is said that the demonstration of the living organisms in water to housewives was much more impressive than lantern exhibitions. Dr. Arnold, writing in August, 1901, states that no cases of Asiatic cholera have been proved to have occurred in Japan since 1896, and acknowledges the assistance afforded to him in his inquiries by Dr. Isaac Nakagawa, professor of bacteriology in the medical school at Sendai, Japan.

#### THE DISTRIBUTION OF PLAGUE.

A TELEGRAM from the Governor of the Cape of Good Hope received at the Colonial Office on Oct. 9th states that during the week ending Oct. 5th in the Cape peninsula there were 2 cases of plague, both in natives, with 1 death. At Port Elizabeth there were 2 cases, both in Europeans, and 3 deaths, 1 of a Chinaman and 2 of natives. The area of infection remained unchanged. There were no military or naval cases. In Mauritius during the week ending Oct. 10th there were 65 cases with 47 deaths.

#### PNEUMOCOCCIC MEMBRANOUS INFLAMMATIONS OF MUCOUS MEMBRANES.

IN an annotation<sup>1</sup> we have recently called attention to the numerous affections which may be produced by the pneumococcus. The subject was very exhaustively discussed by Mr. Alexander G. R. Foulerton at the recent annual meeting of the British Medical Association.<sup>2</sup> But his admirable paper contains no allusion to membranous inflammations of mucous membranes of which the following case, published in the *American Journal of the Medical Sciences* for September by Dr. Charles Cary and Dr. Irving P. Lyon, is a remarkable example. A boy, aged 11 years, was taken ill with sore-throat on Jan. 5th, 1901. On Jan. 7th the throat was reddened and there were incipient signs of pneumonia at the base of the left lung. On Jan. 11th the right base was also affected and an abundant white exudation covered both tonsils. Next day herpes appeared on the lips and the exudation was more or less diffused throughout the mouth and throat. On Jan. 13th there were fibrinous conjunctivitis and subconjunctival hæmorrhage and the lids were swollen and adherent. The mucous membrane of the lips, gums, cheeks, margin and under surface of the tongue, hard and soft palate, fauces, tonsils, pharynx (as far as could be seen), and nose was covered with a continuous white exudation, which could be torn off in shreds, leaving a raw granular bleeding surface. The boy picked at his nose and lips and thus apparently transferred infection from one place to another. On Jan. 15th the glans penis showed the same membranous inflammation as the other parts. On Jan. 16th the anus was involved and membranous shreds were found in the stools. For several days there had been tympanites and the stools had been frequent and soft and had contained considerable mucus. Respiration was laboured from accumulation of mucus in the upper air passages. The sputum contained fibrinous casts of the finer bronchi with dendritic processes, a few red blood corpuscles, and numerous pneumococci. The organism, practically in pure culture, was also found in the exudation on the various mucous membranes. The diphtheria bacillus was absent. The membranes persisted for about four weeks in spite of antiseptic treatment. That the pneumococcus is capable of causing such membranous exudations is attested by various observers. Bristowe in 1879 mentioned that membranous patches on the mucous surface of the large intestine were

sometimes found in pneumonia. Osler, in 1885, reported five cases of "croupous colitis" in 100 necropsies on subjects who had died from pneumonia. In one case the cæcum was covered with a thin layer of adherent lymph and scattered throughout the colon and sigmoid flexure were numerous patches of lymph. Weichselbaum found the pneumococcus in the intestinal croupous exudation in a case of pneumonia. Rochon has described the case of a boy, aged two years, who during whooping-cough developed severe and continued diarrhoea with an eruption of vesicles about the anus. In the fluid of the vesicles the pneumococcus was found in pure culture. During coughing prolapsus recti occurred, revealing in places on the mucous membrane exudation which contained numerous pneumococci. Pneumonia and death followed. Wetter has reported the case of a boy, aged three years, in which during an attack of varicella tracheotomy was required for laryngitis. Membrane was expelled through the tube containing no diphtheria bacilli but pneumococci. Cases of pneumococcic membranous inflammation of the throat, conjunctiva, and nose simulating diphtheria and independent of pneumonia have been recorded. But in most of the cases of pneumococcic conjunctivitis the inflammation could hardly be called membranous, it was characterised by small fibrinous shreds which were sometimes lightly adherent to the mucous membrane. When it is remembered that the pneumococcus is *par excellence* the cause of fibrinous inflammation of the lungs the occurrence of the same process on other mucous membranes should not cause surprise.

#### FISH-CURING.

MOST people know in a general sort of way that herrings are migratory fishes, and that the shoals appear off the Hebrides and then travel in a southerly direction round the coast of Scotland and England. The date at which they first appear is not always exactly the same, but it does not differ to a much greater extent than that of the first appearance of the cuckoo in the south of England or the departure of the swallows from the eastern coasts. The shoals of herrings are followed by fleets of fishing-boats, some of which come from ports as far from the North Sea as Penzance in Cornwall and Brixham in Devonshire. The fishermen who man these boats are, however, not the only people whose movements depend on the migration of the herring. A great many women are similarly affected; they are to be numbered by thousands, and it is to the unnecessary hardships endured by these people that we wish to direct attention. The industry of fish-curing is performed in great part by a nomadic population consisting chiefly of strong and healthy young women, daughters of fisher folk, who go from the north towards the south and return home after their work is done. Some come from places as far north as Stornoway and Shetland. Fraserburgh and Peterhead are the centres of the fish-curing industry in July and August, Scarborough and Grimsby in September, and Yarmouth and Lowestoft in October. To give some idea of the number of people engaged in the work it may be said that as many as 3445 women have been engaged at one time at Fraserburgh, and of these no fewer than 3000 were "foreigners"—for amongst fishing people everyone not born in the place is a foreigner. The work which has to be done is cleaning, salting, and packing the fish for the continental markets. The sleeping accommodation provided for the women is not luxurious, but it is possibly better than many of them enjoy at home—and, according to an official report made by one of the factory inspectors, they live in a state of "marvellous harmony." In Yarmouth the curing trade is carried on in an open space which is undrained and the soil of which is therefore much polluted. Here the work is done in spite of

<sup>1</sup> Fatal Intestinal Hæmorrhage in Pneumonia, THE LANCET, August 17th, 1901, p. 460.

<sup>2</sup> THE LANCET, August 17th, 1901, p. 472.

wind and rain. The processes which precede the making of kippers—the pickling and splitting of the fish—are carried on under cover. The people engaged in the work are crowded, the rooms are often ill-lighted, the flooring is defective, and proper provision is not made for the removal of the refuse. This state of things is not one to be commended and the sanitary authorities of Yarmouth cannot be held to be entirely free from blame in this matter, especially as the land on which the open-air work is carried on belongs to the town, and therefore the civic authorities are the more easily able to make proper restrictions as to its use. It is to be hoped that in the future they will not neglect to carry out such an obvious duty. In France and in Belgium the factory laws insist that the walls and floors of rooms in which organic matter is treated shall be made of impermeable material, and, moreover, they provide for the immediate removal of organic refuse. It would be well if similar regulations existed in England. But in the absence of such a law there is the more reason why those who work at fish-curing should at least have the full measure of protection which is provided for them by the statutory provisions which are already in force in matters pertaining to the public health.

#### A MEDICAL REPORT ON UGANDA.

WE have received a copy of "A General Medical Report on Uganda" by Dr. R. U. Moffat, C.M.G., principal medical officer of the Uganda Protectorate, East Africa. The region included in the protectorate comprises a large tract of country the several parts of which differ entirely in their climatic conditions, varying from the cold and healthy altitudes of the Mau Escarpment to the hot and malarious shores of the Victoria Lake and Nile valley, so that in compiling a comprehensive report Dr. Moffat has found it necessary to take notice of these differences, and he has ably pointed out the main aspects of the various districts into which the country may roughly be divided from the point of view of health. This part of the report is very instructive, but a bare abstract would not be of value and we refer those of our readers who are interested in the matter to the original report. Dr. Moffat further points out that the report may be open to misconception owing to the fact that the Government medical officers at most stations have little to do with the aboriginal natives of the country. For this reason the records based on their work do not afford an entirely trustworthy index of the diseases peculiar to the country. In the great majority of cases the patients treated are alien to the country. Many diseases which, perhaps, are common among the aboriginal tribes may seldom or never occur among the well-fed and better-tended Government employés. On the other hand, these latter may bring with them the seeds of diseases contracted in their own country but which may not be endemic in the Uganda Protectorate. Malaria is endemic through the whole of the western provinces of the protectorate comprising the districts of the Lake level and the Nile valley. The types of fever commonly met with are the tropical quotidian and tertian, the latter more commonly among Europeans. The benign tertian and quartan forms are seldom met with. By far the most important and dangerous form of malaria is that complicated with hæmoglobinuria, the so-called "black-water fever." Dr. Moffat does not discuss whether this condition is indeed malaria or an entirely different disease—as he remarks, his report does not form a suitable occasion for such a discussion; he merely states that he has never seen any reason to connect it with the administration of quinine, and he recommends that in the treatment of the disease the drug should be given speedily and in large doses. Owing to the severe vomiting it is impossible to give quinine by the mouth and

therefore Dr. Moffat suggests that it should be given by intra-muscular injection and describes his method of so administering it. Many other diseases are considered, the most important of which are dysentery and yaws. With regard to the treatment of the latter, Dr. Moffat states that he has had excellent results from the internal administration of mercury. The report should prove very interesting to those who have experience in tropical diseases.

#### SALICYLIC ACID IN WINE.

THERE seems to be little doubt that salicylic acid is occasionally a natural constituent of genuine wine and this observation is of considerable importance in connexion with the preservation of wines by artificial means. In most foreign countries the addition of salicylic acid to wines is forbidden. The fact, therefore, that wines may normally contain the acid is calculated to lead to confusion and not impossibly an injustice might be done, by condemning a wine because it contained the acid which after all may prove to be a natural constituent. The amount of natural salicylic acid in wines is, however, small and no definite evidence of its presence is indicated until five or six ounces are operated upon for the test. It has accordingly been proposed that when seeking for salicylic acid in wine not more than a couple of ounces should be employed for the test. This recommendation has, as a matter of fact, been adopted in Germany. The quantity of salicylic acid in genuine wine is invariably so small that it is difficult to attach any special significance to it in regard to its effect either upon the wine or upon the person who consumes it.

#### BELLADONNA POISONING.

A CORRESPONDENT informs us of the details of a case of poisoning by belladonna brought about by the application of a belladonna plaster. A young lady had been indulging in the sport of duck-shooting and in so doing got very wet. An attack of lumbago followed. A practitioner was not sent for, but whisky was rubbed into the painful region. The pain continued for four days; then the back was rubbed with "Jacob's oil." This only produced a slight redness which disappeared in a few hours leaving the skin quite normal in appearance. On the fifth night a belladonna plaster was applied. The patient wished to go out duck-shooting on the following morning, but when her maid went to rouse her at four o'clock in the morning she was found to be suffering from the characteristic symptoms of belladonna poisoning; her throat and mouth were dry, there was a burning sensation in these parts, and she could scarcely speak, the pupils were widely dilated, and she "had lost the power of controlling her movements ..... and her hands felt as though they were getting smaller." Apparently she rapidly recovered. Several cases of this nature have been recorded. Dr. W. J. Howarth reported one case in THE LANCET of Jan. 27th, 1894, p. 204. A man began to feel that his mouth was dry three-quarters of an hour after putting a belladonna plaster, six inches by four, on his back; the pupils were widely dilated, and delirium of the characteristic type occurred. Idiosyncrasy towards belladonna is not uncommon and many adults are unable to tolerate a dose which a young child could take with impunity. The practitioner who attended the above case is reported to have said that if the patient had not been discovered to have been suffering from belladonna poisoning until four hours later it would "have been too late, in all probability, to save her." We are not aware that a fatal case of belladonna poisoning produced in this manner has ever been reported, and the symptoms have occurred when no previous applications to the back have been made. Our correspondent suggests that it should be made compulsory that a warning should be issued with every plaster sold that serious symptoms may arise in its application, especially if the skin has been abraded. We

think the suggestion a good one, although such cases are extremely rare. It would be still wiser, however, if a druggist was not permitted to sell such a plaster without a prescription from a qualified medical practitioner. It is worthy of note that the emplastrum belladonnæ of the new Pharmacopœia is much weaker than that of 1885. Our correspondent further asks whether a plaster of belladonna and opium would produce the poisonous effects of the former drug. Such a plaster is not official; it would depend in great measure upon the relative strengths of the two ingredients.

#### SOFT WATER AND SOAP.

It is commonly supposed that the use of soft water—rain-water, for example—for washing purposes economises soap. But while it is perfectly true that the lime salts in hard water nullify to some extent the soap by forming insoluble lime soaps, yet the expenditure of soap, at least in toilet purposes, will be found to be considerably less than when rain-water is used, while the cleansing effect is just as good. The explanation of this is that soap is so very readily soluble in soft water that considerably more soap is used than is necessary. Everybody knows the slippery feeling of rain-water in which the hands have been washed with soap, and no amount of rinsing would appear to remove the soapiness from the skin. In this case it is doubtful when soap is used whether, after all, rain-water or soft water is better for the complexion or skin than hard tap-water. It is certainly not so refreshing. In manufacturing processes or in the wash-tub it is true the use of soap in soft water is an economy. It is in this way, of course, that the addition of soda, throwing out the lime salt, saves soap. It has been estimated that if London were supplied with soft water the saving of soap would amount to tens of thousands of pounds per annum, and Glasgow is estimated to save £36,000 annually in the matter of soap since using Loch Katrine water. That may be so, but in the matter of personal washing there is a waste of soap produced rather than an economy by using soft water. The fact that a tablet of soap disappears much more quickly when rain-water is used instead of hard tap-water is proof of this assertion.

#### THE PATHOGENESIS OF DELIRIUM TREMENS.

DR. K. BONHÖFFER of Breslau, in a recent communication to the *Berliner Klinische Wochenschrift* (No. 32, 1901), deals with the pathogenesis of delirium tremens, based upon a study of 250 cases of the disease observed during three years. After referring to the conditions present in the disease—viz., acute hallucinatory mental confusion, transitory albuminuria, dirotism of the pulse, and in fatal cases intense cerebral hyperæmia, and even small hæmorrhages into the brain—he discusses the etiological factors of delirium tremens. Sudden withdrawal of alcohol is one of the factors and injuries (especially cranial injuries) are prone to develop the attack. The presence of epilepsy as a complication increases the liability to delirium tremens in alcoholic subjects. The most potent causes are, however, first, infectious diseases affecting the lungs and respiratory organs, and secondly, gastro-intestinal disorders. Jacobsohn in Denmark and Villiers in Belgium found that 17 or 18 per cent. of cases of delirium tremens were complicated with an acute disease. Tabulating the acute bodily diseases which thus complicate, or participate in the production of, delirium tremens Dr. Bonhöffer found that 20 per cent. were cases of pneumonia, while 23 per cent. included such disorders as acute bronchitis, pleurisy, pulmonary hæmorrhage of tuberculous origin, cellulitis (including erysipelas), paronychia or whitlow, and acute exanthemata; 11 per cent. comprised marked gastric disorder, diarrhoea, and hæmatemesis from cirrhosis of the liver; 10 per cent. were cases of traumatic nature; and 23 per cent.

were complicated with epilepsy. The remaining acute disorders provocative of delirium tremens were rare and amounted altogether to 8 per cent. As regards the pathogenesis of the disease Dr. Bonhöffer inclines to the view that it is of a toxic nature, the clinical form being usually that of acute hallucinatory mental confusion. He also recognises distinct pathological changes in the nerve-cells of the cerebral cortex in fatal cases of delirium tremens, such as chromatolysis, pigmentary degeneration, and vacuolation of the cells, intense capillary hyperæmia of the cortex with minute hæmorrhages into the grey substance, and a hyperplasia of the neuroglia cells, as described by him in a recent publication.<sup>1</sup> The clinical varieties of delirium tremens noted by him are the same as those observed by Evenson, to which reference has already been made in these columns.<sup>2</sup>

#### CLINICAL THERMOMETERS AND THE CASUAL GERM.

A CORRESPONDENT has addressed us upon ground that medical men are careless in cleansing their clinical thermometers. Thus, he says, they support the "Christian Science" doctrine, which seems to us to pertain somewhat to the nature of a "bull," "that there are no germs, but doctors bring them." Now we should be sorry to believe that this patient's experience is at all a common one. Often, he declares, "the thermometer has been stuck in my mouth and dropped back into the case again without a wipe or a wash." Anyone, he very reasonably adds, prefers to see the thermometer washed before and after use. This is no doubt the general practice; there can, of course, be no excuse in any amount of hurry for not at any rate placing the thermometer in water after use and wiping it dry before returning it to its case. Elaborate cleansing is not necessary, nor do we need what our correspondent appears to hanker after, any attempt at sterilisation. The clinical thermometer is not an object that carries gross dirt easily, and therefore water and a clean towel after being used suffice to keep it in decent condition. As regards microbic accompaniment, we may allay our correspondent's fears by assuring him that any thermometer treated as we suggest will not add materially to the microbes that already swarm within his mouth. He is probably in blissful ignorance of the saprophytic condition of his own mucous membrane, and the comparative purity of a glass thermometer. Indeed, he is far more likely to give than to receive in this instance, and if a previous patient also conferred bacterial gifts upon the thermometer these are unlikely to have survived the intervening period between the two occasions when it was used. However, we perfectly sympathise with his protest, considering his unpleasant, and, we trust, unique, experience. After pleading for cleanliness our correspondent concludes with the Jane-Austenian observation that "safety and sensibility alike demand it." We can assure him that the medical profession have no "Pride and Prejudice" in a contrary opinion. It may also allay his apprehension to remember that not infrequently medical men place the thermometer in the axilla rather than in the mouth, although we believe this to be on the whole a less trustworthy position for recording the body temperature, as the instrument is there affected by conditions of perspiration, want of accurate contact, and possibly clothing.

WE understand that the Secretary of State for India has sanctioned an increase of 26 officers to the Indian Medical Service. This will help to get over the difficulty about leave.

THE autumn dinner of the Edinburgh University Club, London, will be held on Wednesday, Nov. 13th, at the Criterion Restaurant. Professor John Chiene, C.B., M.D., F.R.C.S. Edin., will take the chair.

## PROFESSOR VIRCHOW'S EIGHTIETH BIRTHDAY.

PROFESSOR VIRCHOW was born on Oct. 13th, 1821, at Schievelbein, a village in Pomerania. In 1891 his seventieth birthday was celebrated with much enthusiasm in Berlin, and now that he has reached the advanced age of 80 years in the enjoyment of great mental vigour and an amount of bodily energy unusual at his time of life, the anniversary has been attended by manifestations which in their spontaneity and warmth leave no doubt as to the place which he holds in the hearts of his countrymen. Oct. 13th, 1901, was a Sunday. The celebrations began on the previous day with a reception in the new Pathological Institute in Berlin, where the company included the Minister of Education, Herr Studt; the Chief of the Imperial Chancellery, representing Count von Bülow; Baron von Richthofen, the Foreign Secretary; Count Posadowsky, the Secretary of State for the Interior; Herr Möller, the Prussian Minister of Commerce; Herr von Thielen, the Minister of Communications; Dr. von Leuthold, the General Staff Surgeon of the Army; Herr Kirschner, the Chief Burgomaster of Berlin; Dr. Langerhans, the President of the Berlin Municipal Council; and very many representatives of German and foreign medical science. The Minister of Education, Dr. STUDT, said that the name of Virchow would be for ever associated with the Pathological Institute, but in order that future generations might possess a likeness of its founder he, on behalf of the Ministry of Education, presented the institute with a marble bust of him. Professor VIRCHOW expressed his thanks in cordial terms, and then proceeded to deliver an address on the Development of Pathology and the special objects of the institution in which they were assembled. In conclusion, he claimed for pathology a place among the biological sciences. Various micro-organisms were then shown under microscopes and as lantern slides by Professor Koch and others. At 6 P.M. Professor Virchow was entertained at a banquet held in one of the halls of the buildings where the Prussian Diet meets. The company included his wife and several other members of his family, eminent German and foreign men of science, and representatives of the Government. Count POSADOWSKY, the Imperial Home Secretary, proposed the health of the German Emperor. Dr. KOERTE proposed the health of Professor Virchow, and Dr. ALTHOFF of the Ministry of Education presented him with his portrait showing him at the age of seven years as well as with one of his school certificates. The chief event of the celebration commenced at 8 P.M. in the buildings used by the Prussian Chamber of Deputies and was not concluded till long after midnight. This was the presentation of addresses by German and foreign delegations. Professor WALDEYER, who presided and delivered an eloquent address, said that a sum of 50,000 marks (£2500) had been collected for the purposes of the "Virchow Fund" for the promotion of scientific research. Dr. STUDT, the Prussian Minister of Education, then read a letter from the German Emperor to Professor Virchow, warmly congratulating him on the anniversary of his birthday, and eulogising the great services which he had rendered not only to the scientific side of medicine but to its practical application for the benefit of mankind. In conclusion, the Emperor wrote that in recognition of his distinguished labours he had that day conferred on him the Grand Gold Medal for Science and now sent it to him. The Imperial Chancellor, Count von Bülow, also sent a letter of congratulation. The address of the municipality of Berlin was presented by the Chairman of the Municipal Council, Dr. LANGERHANS, who announced that the city had contributed 100,000 marks (£5000) to the "Virchow Fund." The foreign delegates included representatives of medical science from Great Britain, France, Russia, Italy, Austria, and other countries. Great Britain was represented by Lord Lister, who wore the Prussian Order *Pour le Mérite*; Sir Felix Semon (Royal College of Physicians of London); Mr. Howard Marsh (Royal College of Surgeons of England); Dr. Rose Bradford (Royal Medical and Chirurgical Society and Pathological Society of London); Mr. Watson Cheyne (Pathological Society of London); Professor Robert Muir

(University of Glasgow); and Dr. Graham Brown (Royal College of Physicians of Edinburgh).

Lord LISTER, who spoke in English, and was welcomed with hearty applause, said:—

Revered master, I am here as a delegate of the Royal Society of London, of which you are an honoured member, and on behalf of which I have to present to you a loyal address. I have been also requested to hand you addresses from six other societies which greatly regret that it has been impossible for them to send special delegates. They are as follows: (1) the Anthropological Section of the British Association for the Advancement of Science; (2) the University of London; (3) the University of Edinburgh; (4) the Faculty of Physicians and Surgeons of Glasgow; (5) the Medical and Chirurgical Society of Edinburgh; (6) the Royal Academy of Medicine of Ireland. All these bodies join in the recognition of your gigantic intellectual powers, in gratitude for the great benefits that you have conferred upon humanity, and in admiration of your personal character, your absolute uprightness, the courage which has enabled you always to advocate what you believed to be the cause of truth, liberty, and justice, and the genial nature which has won for you the love of all who know you. The astonishing vigour which you displayed in the address to which we listened to-day justifies the hope that, when many of us your juniors shall have been removed from this scene of labour, it may be granted to you to celebrate your ninetieth birthday not only in health and honour but in continued activity in the service of mankind.

Sir FELIX SEMON, who spoke in German, said:—

There are two reasons why I have been selected, dear master, to convey to you the sincere congratulations of the Royal College of Physicians of London. In the first place, the authorities thought it might be agreeable to you if the good wishes of the College were expressed by an old pupil who when he sat at your feet 30 years ago as a young German student did not suppose that he would one day have the honour of representing the venerable College in whose name he now speaks. In the second place, the College selected a native of Germany as its spokesman from a desire to give prominence to the fraternal feeling which has so long existed between German and British scientific men and to express thereby their cordial recognition of the beneficial influence which you have exercised upon science in Great Britain no less than in Germany.

His Excellency Dr. GUIDO BACCELLI, Minister of Agriculture in the Government of Italy, spoke in Latin as follows:—

*Quod reipublicae medicae per orbem bene vertat, et faustum Germaniae felixque sit, tibi, Rodulpho Virchow! hodie, Berolini in novissimo propemodum Scientiarum omnium Capitolio, supremi tribuuntur honores. Immortali igitur lauro, fronte tua redimita, neque splendidiore humanae iustitiae, neque jucundior nobis fulsit unquam dies. Quapropter in tanto doctissimorum virorum tibi plaudentium atque gratulantium Senatu, et ego plaudens atque gratulans, quae per te Italia sentit, promere jubeor.*

*Primum tibi Victorii Emanuelis tertii, amatissimi Regis nostri, nomine loquor, qui fortibus et bonis natus praestanti juventute florens, omnigenae virtutis fulgore, undecumque nitent, trahitur saepe natura. Deinde Ministrorum Regis Consilii nomine in quo praescriptum et qui medicinam politicam hodie feliciter tuetur; et qui studiis italicis ingenio singulari praestat, volunt singulariter memorari.*

*At supereminens omnes, Joseph Zanardelli, libertatis in legem assertor invictus, Consilii Praesul, tibi gloriosissimo affert sua vota per me. Et bene est: tu enim cunctis mirificam intulisti laetitiam, octagesimum annum natus, studiis laboribusque nunquam fractus.*

*Quam vero doctrinam disciplinamque Anatonae pathologicae Joannes Baptista Morgagnius, felici ausu, primus in Italia instituit ac tradidit, tu singulari sapientia in Germania tua perfecisti, eoque egisti ut Magistorum Magister jure voceris. Hoc Itali picturae traditum volvere et ego hexametrum supra tabulam scripsi:*

*"Ut quos corda fovent, praesentes lumina spectent."*

*Io, igitur, triumphe, Rodulpho Virchow! Nestores vive per annos, incolumis florens, terque quaterque beatus. Vive, patriae tuae decus et lumen; vive, humani generis praesidium, vive nationum omnium admiratio, vive Italiae amor, vive immortalis!*

### TRANSLATION.

For the prosperity of the Republic of Medicine throughout the world and for the best interests of Germany the highest honours are vouchsafed to thee, Rudolf Virchow, to-day in Berlin, where Science, in well-nigh all her branches, holds her latest seat. No day has ever shone with purer lustre for the cause of humanity, or with livelier pleasure for ourselves than this, which sees thy brow enwreathed with undying laurel. So amid the plaudits and congratulations of this august concourse of the learned, I too join in applause and congratulations, conveying, on the mandate of Italy, the sentiments she entertains towards thee.

I speak first in the name of our well-beloved King Victor Emmanuel the Third who, sprung from brave and honourable ancestors, with the dew of his youth yet upon him, and radiant with the lustre of every manly virtue, is drawn to thee by his own august nature. Next in the name of His Majesty's Ministers, among whom, in particular, the Minister who happily presides over State Medicine, and his colleague who with rare skill superintends Italian Education, desire to be individually commended to thee.

But, above all, His Excellency Joseph Zanardelli, the indomitable vindicator of "Liberty within the Law," the Prime Minister of Italy, conveys to thee his cordial good wishes through me. Appropriately so; for in thy eightieth year, with strength unimpaired by studious research and by energetic action, thou inspirest us all with equal wonder and delight.

In truth the theory and practice of pathological anatomy, first in Italy imparted and diffused with happy initiative by John Baptist Morgagni, has by thee, in thy native Germany, been carried to such rare perfection that thou hast justly earned the title of Master of Masters. This achievement Italy desires to commemorate by the painter's art and I, on the picture, have ventured to inscribe the hexameter—"that the eye may behold him as present whom the heart cherishes."

So then, "Io Triumphe!" Rudolf Virchow. Live, through the years of a Nestor, in health and energy, thrice, aye four times, happy. Live, as thy country's ornament and light; live, as a safeguard of humanity; live in the admiration of all nationalities; live in the imperishable love of Italy!

The following telegram, also in Latin, has been sent to Professor Virchow by the president and vice-president of the Federal Council of the Medico-Chirurgical Orders of Italy:—

Prof. Rodolfo Virchow, Berlino.  
Durante, Bastianelli, Sciamanna, Spaziani, Topai, Praesides foederati consilii Italicorum medicorum ordinum, plaudentes, tibi, pathologorum principi, salutem dicunt, eo temporis momento, quo omnes orbis terrarum medicinae cultores suam quisque admirationem verbis effingunt—voti expetentes ut altiora tua studia magis magisque efficacis artis medicae officium sint redditura.

Dabant Roma a. d. IV Idus Octobres A. P. Chr. n. MDCCCXI.  
12. X. 901.

[TRANSLATION.]

To Professor Virchow, Berlin.  
Durante, Bastianelli, Sciamanna, Spaziani, Topai, presidents and vice-presidents of the Federal Council of the medico-chirurgical orders of Italy, salute and applaud thee, prince of pathologists, on this day when all the votaries of the healing art throughout the civilised globe convey to thee in words their admiration of thee collectively and individually, in the hope and desire that thy researches, prosecuted with ever greater profundity, may render the function of medicine yet more and more effective.

Rome, Oct. 12th, MDCCCXI.

On the evening of Sunday, Oct. 13th, Professor Virchow was present at a birthday dinner in the Palace Hotel, Lord Lister and Sir Felix Semon being among the guests. In the Schellingstrasse, where his residence is, the houses were illuminated in his honour.

## THE NEW PATHOLOGICAL LABORATORIES AT THE UNIVERSITY OF OXFORD.

ON Oct. 12th, an appropriate date, being the birthday celebration of Professor Virchow, the new pathological laboratories of the University of Oxford were opened. Among those present were the Vice-Chancellor of the University, Mr. D. B. Monro. Provost of Oriel (who presided), Sir William Church, Bart. (President of the Royal College of Physicians of London), Sir J. Burdon Sanderson, Bart. (Regius Professor of Medicine), the Warden of All Souls, the Dean of Christ Church, the Rector of Lincoln, the Master of Pembroke, the Provost of Queen's, the Principal of Brasenose, the President of Magdalen, the Warden of Keble, Dr. G. Sims Woodhead (professor of pathology in the University of Cambridge), Mr. W. Bruce Clarke, Dr. F. H. Champneys, Dr. J. F. Payne, Professor Arthur Thomson, Professor E. B. Poulton, Professor W. Odling, Professor W. Esson, Professor J. McFadyean (Royal College of Veterinary Surgeons), Dr. H. D. Rolleston (St. George's Hospital), Mr. Horatio Symonds, Dr. James Ritchie (reader in pathology), the Senior and Junior Proctors, Professor Wright, Professor E. J. McWeeny (Dublin), Dr. H. P. Hawkins (St. Thomas's Hospital), Dr. J. W. Washbourn, Dr. W. Bulloch and Dr. G. Schorstein (London Hospital), Dr. M. S. Pembrey (Guy's Hospital), Dr. Ogle, Dr. S. West, Dr. Theodore Williams, Professor R. F. C. Leith (Birmingham), Professor Sheridan Delépine (Manchester), Dr. J. Neil, Mr. A. J. Freeborn, Mr. W. W. Fisher, Mr. P. F. Willert, and others.

The buildings stand in the museum grounds and a full account of them, together with plans, appeared in *THE LANCET* of June 23rd, 1900, p. 1823. The architect was Mr. J. A. Souttar of Bishopsgate-street, London, E.C.

The VICE-CHANCELLOR, having referred to the growth of natural science study in the University and to the good work done by the late Regius Professor of Medicine and the late Professor Rolleston, called upon Dr. J. Ritchie, the reader in pathology, to give some account of the work.

Dr. RITCHIE said it was natural to think of the time when the University voted the money for the building of a department of pathology, and in carrying out the work the University had the advantage of the experience and advice of two of its members, than whom there could not be greater experts in the details of such work. One was the Regius Professor of Medicine who not only looked upon the scheme from the standpoint of his official position, but all along he had given to it the advantage of the vast stores of experience that he possessed as to what ought to be provided in such a department. The other gentleman to whom the University owed much in this connexion was Professor Arthur Thomson. In the actual building fabric they had two things to keep in view, two objects for which such a building ought to

be made available. The first was to meet the requirements of those preparing for graduation in medicine. The University of Oxford had by recent regulations made the subject of pathology one of very great importance in the second Bachelor of Medicine examination, which was such as was required in very few examining institutions in this country. Therefore, the first thing they had to think of was the proper provision and accommodation for teaching the subject, and so they had that lecture-room and other rooms which were necessary for students to obtain that practical acquaintance with the details of the science of pathology on biological lines which they ought to have. The greater part of the necessary studies along these lines was of a microscopical nature, and therefore they had to provide rooms where the students could become practically acquainted with the subject. They had had to make provision also for students obtaining an adequate knowledge of the bacteriological department. One matter which they had to consider very seriously was that the standard for graduating in medicine in the University was very high, and they had had to face the question of the possibility of many men coming back here to work after having graduated. Here, therefore, was provided a complete chemical laboratory where researches could be carried on; they had tried to meet the actual requirements of every branch of research or to arrange matters so that any requirements could be very easily met in the future. They had also had to make provision for the accumulation of specimens the custody of which the University had made over to this department. Upon this point he should like to refer to the intimate connexion which had been made between the Radcliffe Infirmary and this department, and they hoped that the work would be for the benefit of the inmates of the Radcliffe Infirmary, as a great part of it would be in the way of confirming the diagnosis of the medical staff. Dr. Ritchie concluded by referring to the admirable manner in which the architect had designed the building and to the munificence of Dr. E. R. Frazer, of Balliol College, who had given £5000 towards the expenses.<sup>1</sup>

Sir W. S. CHURCH, Bart., President of the Royal College of Physicians of London, next delivered an address. He traced the teaching of modern medicine in Oxford from the time that Sir Henry Acland brought the museum into being and made a graceful reference to the occasion on which they were met, being also the day on which the eightieth birthday of the Nestor of Pathology, Professor Virchow, was being celebrated. Pathology and physiology were interdependent. The days of opposition to the study of the natural sciences in the University had, happily, long since passed away, and they were more nearly approaching the ideal the originators of the museum had before them. But yet much remained to be added before the University was fully equipped for, to use the words of Mr. Ruskin, "the reverent and earnest study of nature and of man, to the glory of God, to the better teaching of the future, to the benefit of our country, and to the good of all mankind."

Professor G. SIMS WOODHEAD, Professor of Pathology at Cambridge University, after announcing that a telegram of heartiest greetings had been sent from the meeting to Professor Virchow, congratulated the University on her new Laboratory.

The REGIUS PROFESSOR OF MEDICINE, in moving a vote of thanks to the Vice-Chancellor, said it was a fact of happy augury that he was the grandson of that Professor Alexander Monro who founded both the Edinburgh Infirmary and the Edinburgh Medical School.

## NOTIFICATION OF DEATH TO THE CORONER.

WE have received a voluminous correspondence which was evoked by the preliminaries of the inquest on the late Right Hon. W. W. B. Beach, M.P. It will be recollected that this gentleman, who had attained a great age, was thrown out of a hansom cab in Parliament-street on August 2nd and died at 8.45 P.M. on August 3rd in Westminster Hospital, to which he was admitted immediately after the accident. Here it is well to point out that August 3rd was a Saturday and August 5th was a Bank Holiday. On the evening of August 3rd the

<sup>1</sup> *THE LANCET*, July 7th, 1900, p. 39.

house physician, Mr. A. R. Roche, drew up a properly-worded intimation of the death and sent it to the private residence of Mr. Troutbeck, coroner for Westminster. The next morning (Sunday), hearing that the coroner was out of town, he obtained his temporary address and telegraphed the facts of the case. About 11 A.M. on August 5th a reply was received from the coroner stating that an inquest would be held on August 7th, and in answer to this Mr. Roche telegraphed that decomposition was setting in. On August 7th, before the inquest commenced, the coroner, we understand, sent for Mr. Roche and in a private room spoke to him in a manner which he (Mr. Roche) resented as "unjustifiable." Mr. Roche very properly refrained from any contention with the coroner and confined himself to sending to the hospital secretary a written statement of the circumstances as seen from his point of view. The secretary's reply to this communication contained the passage, "I am directed to inform you that the House Committee consider that your action in communicating with the coroner regarding the death of Mr. Beach was entirely correct," a sentiment which was repeated in other words at a later stage. It appears that the coroner for Westminster considers that information of a death ought to be given not to the coroner himself but to the coroner's officer. The authorities of Westminster Hospital have, however, been guided by the strict letter of the Coroners Act, and on August 15th the secretary wrote to the coroner that it had been "the practice at this hospital for the past 24 years, and doubtless for a very much longer period, to give information to the coroner direct." The reply was as follows:—

Coroner's Office, Phillimore Chambers,  
21, Great Smith-street, S.W.  
16th August, 1901.

S. M. Quennell, Esq.  
Dear Sir,—To deal with the question of construction of an Act of Parliament first. I fear that the logical position in which you have placed yourself is untenable.

The Act does not refer to the coroner's officer, therefore there is no officer! Such is the argument.

The proper way to inform the coroner is to do it in the manner in which he asks.

The proper course has been pointed out many times. It is the course adopted with great success by other hospitals.

Unless and until these notices are sent from the secretary's office at once directly to the officer there always will be confusion. The resident officers are not instructed by anyone in these duties, and, of course, they bungle like any other inexperienced young men.

It must obviously cause delay not to send direct to the officer, because a report must be made in each case by him to enable the coroner to make his decision. The other matter of the particular case of Mr. Beach is far more serious than you appear to be aware of.

Owing to the action of the house physician in not reporting this death to me or to the officer or any other person until by telegram on Sunday afternoon, when, as he admitted, he knew it could not reach me until Monday morning, complaint has been made of the delay to the Home Secretary, and Sir Michael Hicks-Beach tells him that the coroner was informed "at once" of the death, and that reasons were given then for taking the inquest very soon. Both of which statements are untrue. Now these statements could only be made by a man in his position on the strength of information given by some person at the hospital.

I want an explanation of the whole circumstances.

I also think that the House Committee ought in their own interests to ascertain how such statements came to be made.

The reason alleged for the hurry being that the body was decomposing makes the position all the more inexplicable, since this body was actually left in the hospital full of patients in an open coffin to within a quarter of an hour of its removal for the purpose of the inquest on Wednesday.

It is true that putrefaction had set in, as alleged, on Monday morning, it is perfectly disgusting that the house physician did not insist upon the body being removed to the parish mortuary at once.

Yours faithfully,

J. TROUTBECK,  
Coroner for Westminster.

From inquiries which we have made there would seem to be no doubt that, technically speaking, notice of death should be given to the coroner, but that, as a matter of fact, this is seldom done anywhere, as in practice it is found to be very inconvenient and often to cause delay in the holding of an inquest. The practice generally adopted is to notify the coroner's officer who at once makes inquiries and reports the facts to the coroner for his decision. By sending directly to coroner the necessity arises of forwarding the letter to the officer, who may not receive it till the next day, and then he may have to make inquiries and to report to the coroner on the following day, thus causing two days' delay, which may be very unpleasant for the relatives.

As we have said above, the practice at Westminster Hospital is to give information directly to the coroner, but it is evident that to the coroners generally this practice does not commend itself, and perhaps not without some cause, for there does not seem to be any particular reason, save always the verbatim interpretation of the words of an Act of

Parliament, why hospital authorities should not notify the coroner's officer instead of the coroner himself. Therefore we can to some extent understand the position taken up by Mr. Troutbeck in his letter, which, however, bears traces of having been written in haste and is certainly lacking in urbanity. It should be explained that the hospital authorities deny that the body was "left in a hospital full of patients in an open coffin," and the House Committee informed the coroner that he was "mistaken in suggesting that it was perfectly disgusting to allow the late Mr. Beach's body to remain in the hospital for so long a period." The body lay in a mortuary chapel which is completely cut off from the hospital proper and the coffin was screwed down on the morning of Monday, August 5th. It was more in harmony with the wishes of Mr. Beach's family that the body should remain there than be removed to the parish mortuary.

At one hospital we are informed that the authorities have a special card printed, which is filled up in the steward's office, giving the necessary particulars, and is then sent directly to the coroner's officer. Some such arrangement as this, we think, the best one to adopt and would have saved the unpleasantness to which we have referred. Mr. Roche merely followed the custom in vogue at his hospital and no blame can attach itself to him. But it would be well for the hospital authorities on the one hand, and the coroner on the other, to come to some mutual understanding as to the course to be pursued in the future.

## SANITARY WORK IN THE PORT OF LONDON.

DR. WILLIAM COLLINGRIDGE, the recently-appointed medical officer of health of the City of London, was previously for a period of 20 years medical officer of health of the Port of London—namely, from 1880 until the year 1901 was somewhat advanced. He is therefore the author of the report of the medical officer of health of the Port of London for the half-year ending June 30th, 1901, and he prefaces it with a brief historical retrospect. In 1880 the medical staff consisted of a medical officer of health and a medical practitioner who gave a portion only of his time to the care of patients admitted into the hospital ship *Albin* lying off Gravesend. At the present date the medical staff consists of a port medical officer, three boarding medical officers at Gravesend (one of whom is in charge of the hospital on shore), and one medical officer stationed at Sheerness. During the year 1880 there were 16,341 vessels inspected; during 1900 this number had risen to 31,224. In 1883 the boundaries of the jurisdiction of the port were greatly increased and were made to include the mouth of the Medway. To meet the wishes of the Rochester port authority by inspecting all vessels arriving from foreign voyages, a medical officer has been stationed at Sheerness who boards all vessels reporting. In 1892 the great development of the port sanitary authority took place. Cholera appeared on the continent, and the Customs had no means of coping with the imminent danger of importation of this disease. A medical officer was, therefore, stationed on the Customs' hulk off Gravesend, whose business it was to visit every vessel on arrival, and what was only intended as a temporary measure became a permanent one, the whole of the machinery for dealing with infectious disease passing from the hands of the Customs to the corporation as port sanitary authority. The Public Health Amendment Act of 1896 abolished the last vestige of quarantine and laid the whole duty of the protection of the ports of this country upon the local authority, acting under the supervision and control of the Local Government Board. The report for the half-year ended June 30th, 1901, with its appendices fills 60 large pages. It shows that during that period 16,376 visits of inspection were made to vessels of all classes within the port, 7361 lying in the river and the remainder in the various docks. Of the total number, 13,433 (equal to 82 per cent.) carried the British flag, the Norwegian coming next in numerical order with 1020 (equal to 6 per cent.). The boarding medical officers at Gravesend visited 5141 vessels, 476 of which were medically inspected, this involving the personal inspection of 13,255 passengers and 35,626 persons forming the crews. The cases of infectious disease dealt with were 157 in number—namely, eight of small-pox, four of scarlet

fever, 18 of diphtheria, 28 of enteric fever, 80 of measles, and 19 of other infectious diseases. Ten men forming part of ships' crews were found to have enlarged or suppurating inguinal glands and as a precaution against plague were removed to the port sanitary hospital for observation, but bacteriological examination gave negative results. Dr. Collingridge quotes the memorandum of the Local Government Board relative to ship-borne rats and plague, and devotes several pages to this question. Experiments, he says, have been made by the Clayton Fire Extinguishing and Ventilating Company, Limited, one being on the s.s. *Manora* in the Royal Albert Dock. The vessel was empty at the time and the method consisted in pumping sulphurous acid gas from a special apparatus into the hold. This system is effective in destroying rats and has the great advantage of limiting the risk from fire which always obtains when sulphur is burned on shipboard, but it may be detrimental to the cargo. On the *Manora* 303 dead rats were found after treatment of the vessel. Experiments with the cocco-bacillus of Dr. Danysz were made in the Royal Victoria and Surrey Commercial Docks. Bread soaked in the virus, and also the bodies of guinea-pigs and mice which had died from inoculation with the bacillus, were deposited in the warehouses and were devoured by the rats but without producing any observable effect on them. Large numbers of rats were, however, destroyed by means of traps and poison. From Feb. 28th to June 30th the total so destroyed was 32,008, of which about 20,000 were killed on board vessels and about 12,000 in warehouses.

### THE POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.

THE new college building of the Post-Graduate College at the West London Hospital, Hammersmith, was formally opened by Sir WILLIAM MAC CORMAC, Bart., K.C.B., K.C.V.O., on Oct. 14th in the presence of a numerous company.

Sir WILLIAM MAC CORMAC in the course of his address said that they had not yet reached the condition denoted by that somewhat misused term "perfection." They would continue in the future to realise further progress just as they had realised advances in the past. Medicine was a progressive science and those who practised it could not stand still. They must ever continue to learn; indeed, they all must do so unceasingly if they would not be hopelessly left behind, and in an institution like that which they were in the opportunity was given. The staff of the West London Hospital was young and energetic and might well be congratulated on the progress which it had made. Many years ago there was some question of establishing a complete medical school, but the plan was, fortunately, abandoned, since there were a sufficient number of such institutions in London and the cost to the smaller schools of teaching subjects like chemistry, anatomy, and physiology was practically prohibitive. The much more promising project of a post-graduate school subsequently took place, and from small beginnings, consisting in the delivery of weekly lectures without any clinical advantages, had now achieved a very considerable success. A feature in the school was that it was reserved exclusively for qualified medical men. Unqualified students were not taught by their side, nor, indeed, would the same class of teaching be suitable for both. The natural diffidence of the older student was spared the comparison of his own mistakes and shortcomings with the complete absence of any such weakness in his younger brother. The wards and hospital practice were open to all the post-graduates. Special clinical lectures were given, lectures were daily delivered in the lecture-room, and classes of instruction in various special subjects had been formed, limited in each instance to 10 persons, who could thus readily acquire the knowledge they desired. All this had been proved to be of great service to a large number of general practitioners of London and the suburbs, and to country medical men as well, who found the opportunity of doing occasional hospital work useful and agreeable. Many officers of the navy and army had availed themselves of the opportunities here afforded. Work of a similar kind was being done elsewhere, but the West London Post-Graduate College was the only one enjoying the advantage of a close

connexion with a general hospital, and the only one where the practice was reserved for the benefit of qualified men alone. Opportunities were given to the students of personally examining the patients before the cases were discussed, and those interested in surgery could assist at operations in the theatre and do work as dressers in the wards. A considerable number of the medical officers serving in South Africa had previously attended the post-graduate instruction there, and had written in terms of grateful acknowledgment of the value it proved to them. Nearly all of these officers attended without having previously obtained any leave from their ordinary duties, which had to be attended to. Some of them came three or four times a week from places like Aldershot, Chatham, and Woolwich, at much personal inconvenience to themselves, and several naval medical officers during their leave ashore had also attended to their great credit. The need for the school would be more and more recognised, not only in the medical element of the public services, for whom study leave in the near future should be a recognised institution, but for civil practitioners as well. When the medical history of the war came to be written justice would be done to the medical officer, who had displayed a complete devotion to duty and a complete self-sacrifice. He accomplished much, and in an admirable manner, under restrictions and difficulties which it was very hard adequately to appreciate, and the results accomplished would bear the most favourable comparison with those of any other war or expedition, and, as recently seen in China, with the medical services of other nations. The war had caused the generals and commanding officers to see with their own eyes what medical officers did, and there had been many strongly commendatory reports sent home, while very generally a greater sympathy and appreciation had been shown by the combatant ranks for the work of their medical brethren. In regard to the manner in which the medical staff as a whole acquitted themselves in the face of the tremendous responsibility which they had suddenly to face Lord Romer and his colleagues on the South African Hospitals Commission had vindicated the high reputation of the Army Medical Corps. If there were failure in some instances the cause was the pressure of circumstances which baffled the devotion of the medical officers. Some means should be devised for removing the Army Medical School from its isolated position at Netley to London, where they would feel the constant stimulus of competition and of criticism, and be made free to benefit by the unrivalled teaching and clinical opportunities which the great city afforded. If a great military hospital and school of the most modern and complete type were established in London, and a body of teachers similar to that of the Kaiser Wilhelm Institute in Berlin, where post-graduate instruction of the army medical officers was most complete, were appointed in connexion with it, a more widely reaching influence would be exerted for the improvement and advancement of the medical department of the army than any other single measure could accomplish. It would enable a considerable proportion of the army medical officers to keep in touch with the scientific work of the London schools and Netley Hospital could still be used for the reception of invalids from abroad. That or any other suggested improvement altogether depended on the ability of the authorities to fill up the vacancies in the department and to create a medical corps of sufficient number. The scheme would probably be the means of effecting a closer relationship between the military and civilian members of the profession. In the South African war the services of civilian practitioners were largely drawn upon, and that would be the case in any future war.

### REPORT OF THE COMMISSIONERS IN LUNACY FOR SCOTLAND.

In the forty-third annual report of the Commissioners in Lunacy for Scotland it is stated that the number of the insane in Scotland on Jan. 1st, 1901, under official cognisance was 15,899. Of this number 2395 were private patients, 13,458 were paupers maintained by parochial rates, and 46 were maintained at the expense of the State. In January, 1858, when the Commissioners in Lunacy for Scotland entered on their functions, the total number of lunatics officially known to the board was 5824, and since then the number of lunatics under their jurisdiction has increased

to two and three-quarter times the original number. The increase of the population during the same period has been 42 per cent. "The proportion of all pauper lunatics per 100,000 of population shows an almost steady increase since 1858 and at the beginning of this year attained its highest figure of 308," as against the next highest, 304, which was attained last year. As regards the number of persons admitted into asylums, excluding mere transfers from one institution to another, it is shown in Table VII. of the report that the number of private patients admitted during the year 1900 was 542, being 20 less than in the preceding year and one more than the average for the quinquenniad 1895-1899. The number of pauper patients admitted during the year 1900 was 2899, being 31 more than the number during the preceding year and 160 more than the average for the quinquenniad 1895-1899. During the year the total number of pauper patients discharged as recovered amounted to 1276, or 12.2 per cent. of the average number resident. The number of deaths in the same class of patients was 958, or 9.2 as calculated on the same basis. Of a total of 102 accidents reported as having occurred to patients during the year, in 13 cases the termination was fatal, death in four of these cases being due to suicide by hanging or cutting the throat. In one case of suicide by a patient leaping into a river the nurse, Miss Isabella Sime, also lost her life in an heroic effort to save the life of the patient under her charge. In 48 cases the accidents involved fracture of bones or dislocation of joints, and in 23 cases injuries to the head. There are two training schools for imbecile children, one at Baldovan and the other at Larbert. These institutions receive between them about 380 children, but both appear to be overcrowded, and further accommodation is needed. In Section X. of the report the commissioners deal with the question of general paralysis. During the five years 1896-1900 the total number of deaths from general paralysis amounted to 667, including 550 males and 117 females. Of the male patients, 40 per cent. had died from the disease between the ages of 31 and 40 years, and 39 per cent. had died between the ages of 41 and 50 years. For females the corresponding proportions were 39 per cent. and 33 per cent. Comparing these figures with those of the decennium 1865-1874, it appears that some support is lent to the view that there is an increase in the number of deaths from general paralysis during early adult life and the middle periods of life—i.e., in the decades 31 to 40 and 41 to 50 years. Of the total 667 patients who died from general paralysis during the period 1896-1900 the length of residence in asylums was three years and under in 605 cases, or 91 per cent. In 54 cases the duration of residence was from three to five years, in seven it was five to 10 years, and in one case it was over 10 years. The expenditure on maintenance per head of pauper lunatics has risen steadily since 1895, and the rise still continues. The expenditure for the purchase of land and the erection of asylums also continues to increase year by year without abatement.

## THE THIRTIETH ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD, 1900-1901.

### I.

#### THE FOOD AND DRUGS ACTS AND THE QUALITY OF THE METROPOLITAN WATER-SUPPLY.

THERE are certain fresh features in the sections of the annual report of the Local Government Board just issued relating to the administration of the Food and Drugs Acts and to the metropolitan water-supply which are of interest and worthy of note. The Sale of Food and Drugs Act of 1899—a really important addendum to the existing laws—came into operation on Jan. 1st, 1900, and seeing that this Act contained several important changes in the law relating to adulteration of food it is interesting to learn in what manner the new legislation has affected the administration of this important department of public service. The chief result would appear to have been—and that is satisfactory so far as it goes—that many more samples have been taken for analysis. Indeed, during 1900 many local authorities for the first time in their existence

obtained samples for analysis, whilst others have been induced largely to increase the number hitherto taken. It is with considerable satisfaction that we note that the Local Government Board have at length stirred up those authorities of districts in which the work done was inadequate, urging upon them to exercise the powers entrusted to them by the legislature for the suppression of adulteration. It is to be hoped that this activity in thus reminding the authorities of the duty specifically cast upon them will be maintained, for we cannot admit even now that the number of samples analysed in relation to the population is sufficient. Moreover, with the increase of the number of samples taken for analysis there invariably appears a decrease in the number of samples found to be adulterated. The past official year again gives evidence of this fact, for something like 10,000 samples in excess of the number taken in the previous year were obtained for analysis and the result shows a diminution in adulterated samples of 0.6 per cent.; that is to say, the percentage adulterated in 1899 was 9.4, while in 1900, with 10,000 more samples taken for analysis, it was 8.8. The number of samples examined was 62,858, of which 5503 were reported against and proceedings were instituted in respect of 3321. Just as there has been a decrease in the number of metropolitan medical officers of health consequent on the operation of the London Government Act, 1899, so there has been a similar decrease in the number of analysts for metropolitan boroughs. The number of analysts whose appointments were approved by the Local Government Board was 237. As in previous years the bulk of the samples analysed consisted of milk, the proportion reported against (namely, 10.8 per cent.) being slightly higher than the average of the previous six years—a result which may be attributed to the remarkable drought. It will be interesting to learn in what way the rate of adulteration of milk will be affected by the recent adoption of a standard for milk. To some extent the important increase in the total number of samples analysed was due to the occurrence of arsenic in beer in Manchester and certain other places in November last year. It is satisfactory to record that the analytical equipment of the country proved equal to the occasion and "within 30 hours," writes the analyst for Lancashire, "of the source being made known in the neighbourhood of Liverpool samples of glucose and of beer were in the hands of the public analyst. Within a few days most of the dangerous glucose was withdrawn from use. In less than three weeks most of the beer in and near large towns was either destroyed or withdrawn from sale prior to destruction, and although in places more remote from the centre of activity and from the great brewing centres the harmful beer lingered longer, yet after three weeks there was only here and there a sample to be found in the country districts." During the year no less than 4559 samples of beer were thus submitted to analysis. A curious and contemptible mode of adulteration is reported by the analyst for Cornwall. He noticed that a portion of a small cheese submitted to him had an unusually thick rind. While the cheese itself would have been passed as genuine the rind was found to contain no less than 69 per cent. of barium sulphate, a very heavy white substance. There is no doubt that as cheese is sold by weight the barium sulphate was added to increase its weight.

We note with satisfaction that Dr. Thorpe has considered it advisable in the public interest to institute a tri-weekly examination of the metropolitan water companies' supplies instead of a monthly chemical examination as was the plan pursued by his predecessor, the late Sir Edward Frankland. Further, samples are now collected at various points in the districts supplied by the different companies and not as hitherto always from the same place. We have urged the desirability of this plan of control repeatedly in our columns. Dr. Thorpe admits, however, that the tri-weekly examinations are only partial, being confined to the determinations of the amounts of oxygen consumed and albuminoid ammonia, these data affording, in Dr. Thorpe's opinion, trustworthy indications of the variations in the proportion of organic matter present in the waters. At the same time when the samples were not perfectly clear the turbidity was examined. The monthly analyses reported by Sir Edward Frankland were laborious on account of his confidence in the method known as the combustion method for the determination of the organic carbon and organic nitrogen in the water. Sir Edward Frankland, as was well known, would not recognise that the albuminoid ammonia process was of any value. Thus the

difference of opinion on this point between Sir Edward Frankland and Dr. Thorpe has enabled the latter to undertake the analyses of water more expeditiously by adopting the quick albuminoid ammonia and oxygen absorbed processes in place of the tedious combustion process. In our opinion the number of samples submitted to analysis might be further increased with advantage and the results should be published without unnecessary delay. Dr. Thorpe, however, by no means belittles the combustion process for the determination of organic carbon and organic nitrogen, for he says that the results gained are of great value as they afford the chief data on which the probable origin of the organic matter is determined. But the process takes time. During the year there were a number of occasions when sensible turbidity was observed in the waters, but in nearly all cases the turbidity was very slight indeed and consisted mainly of rust-stained particles in all probability introduced by the disturbance of the water. 14 out of 16 samples of the Grand Junction Company's water collected during the months of August, September, October, and November, were distinctly opalescent with very finely divided oxide of iron due, as was afterwards explained by the engineer, to the proximity of the collecting place to the dead end of a main. The defect was subsequently remedied, as shown by the later samples drawn being almost invariably clear. It is regrettable, we think, that bacteriological examinations are omitted, although Mr. Perrin, the official water examiner, expresses the hope that the recommendations of the Royal Commission presided over by Lord Llandaff, to the effect that small bacteriological experimental works should be established in order to ascertain what processes of treatment give the best results and what bacterial standard of effectual filtration can be reasonably adopted for practical use, will receive the early attention of the companies concerned. Dr. Thorpe remarks that it is obvious that the organic matter present in the raw Thames and Lee waters must be partly of vegetable and partly of animal origin, as the surface and other drainage from the cultivated land and the effluents from the sewage works of towns situated on or near the rivers are discharged into the streams. He admits that under ideal conditions the use of water subject to such regular pollution would be avoided, but adds the very safe remark that provided certain flood water is excluded and provided that after proper storage the water is efficiently filtered the risk of danger to the public health through consuming such water is reduced to a minimum if not to zero. Of course, it is a well-known fact that the water-supply of London drawn from the river Thames and the river Lee has only been and is only now made safe for drinking purposes by efficient filtration, and since that is so, it is most important that the filtration processes should be closely studied and watched and kept under the strictest possible control.

### MEDICAL SCHOOL DINNERS.

*St. Bartholomew's Hospital.*—The annual old students' dinner took place in the Hospital Hall on Oct. 1st, when 158 sat down to dinner, Mr. W. J. Walsham being in the chair. Among the guests were Sir Trevor Lawrence, Sir William Mac Cormac, the Hon. John Collier, Sir Henry Norbury, Professor Clifford Allbutt, and the Principal of the London University. The event of the evening was the presentation to Sir Thomas Smith of a subscription portrait painted by the Hon. John Collier. The Chairman, in presenting it, expressed the double feeling which inspired the subscribers of admiration for Sir Thomas Smith's professional qualities and affection for his personal qualities. Sir Thomas Smith begged Sir Trevor Lawrence to accept it on behalf of the Governors and proposed the painter's health. The toast of "The Services" was proposed by Mr. Bowlby, and replied to by Sir Henry Norbury, K.C.B., Director-General of the Royal Navy, and Colonel Hendley, I.M.S. Sir T. Lauder Brunton proposed "The Visitors," to which Professor Clifford Allbutt and the Principal of the London University replied.

*Charing Cross Hospital.*—The annual dinner of the past and present students of the Charing Cross Hospital was held on Oct. 2nd in the Victoria Hall of the Hotel Cecil. The chair was taken by Mr. C. Gibbs. The guests, who numbered over 250, were able to converse with one another after the dinner, for which unusual facility they had to thank

the honorary secretaries, Dr. H. S. Clogg and Dr. W. H. Unwin, who had arranged a short toast list. Professor Taylor proposed "The Staff of Charing Cross Hospital and Medical School," to which Mr. J. A. Bloxam replied. Dr. Eden in a witty speech gave "The Past and Present Students," which was replied to by Mr. Hopewell Smith and Mr. G. E. Bellamy. The toast of "The Visitors" was given by Mr. F. C. Wallis and was responded to by Mr. Anthony Bowlby.

*St. George's Hospital.*—The annual dinner was held at the Whitehall Rooms on Oct. 1st. The chair was occupied by Mr. J. Warrington Haward, consulting surgeon to the hospital, and 130 guests were present. The chairman proposed the usual loyal toasts and also that of "The Medical School." Dr. Isambard Owen, the dean of the school, responded for the latter. The health of Dr. P. W. Latham of Cambridge, who had given the introductory address but was unfortunately prevented from attending the dinner, was proposed by Dr. W. H. Dickinson. Mr. A. Marmaduke Shield proposed "The Past and Present Students," the toast being responded to by Dr. F. M. Hawkins and Dr. W. L. Ascherson. "The Health of the Governors" was proposed by Mr. Turner and replied to by Mr. Holmes, the treasurer of the hospital. The deputy treasurer, Mr. A. W. West, proposed "The Health of the Chairman." The guests included the senior physician and senior surgeon, Dr. W. Ewart and Sir W. H. Bennett, and other members of the acting and consulting staff, together with Surgeon-General Penny, Deputy Inspector-General Wood, Colonel H. E. Drake-Brockman, Colonel Wilson, Colonel A. W. F. Street, and Colonel G. D. N. Leake.

*Guy's Hospital.*—The annual students' dinner was held on the evening of Oct. 1st and was largely attended. In the absence of Dr. P. H. Pye-Smith the chair was occupied by Dr. F. Taylor. The Chairman, in proposing "The Students' Club," said that there was no doubt about the success of the Students' Club, which was now something like 20 years old. The toast of "Guy's Hospital" was next proposed, coupled with the name of Mr. Cosmo Bonsor. Dr. Taylor said that there was an old saying that "Wherever you go, whether to New Zealand, or Timbuctoo, or Greenland, or Kamtchatka, or even to the North Pole, there you will find a Guy's man." They knew to their cost that there had been a great many Guy's men in South Africa. They might perhaps know that a Guy's man was at that moment accompanying the Duke and Duchess of Cornwall and York at the other side of the Atlantic. Mr. Cosmo Bonsor, in responding to the toast, said that he always considered it a very high honour to have his name coupled with Guy's Hospital. Dr. Taylor had spoken of South Africa, and there was one amongst them that night, Dr. S. E. Denyer, who had been distinguished for having gallantly done his duty in the field there. Last year they had welcomed home from South Africa their friend Mr. A. D. Fripp who had a great deal to do with the Students' Club but was not present with them that night. They were also extremely proud to see Dr. J. W. Washbourn, who had returned home and who made a great name for himself in South Africa and for the school where he learned to work—Guy's Hospital. Their friend Dr. F. E. Fremantle was also amongst them. He could say a great deal about the ladies who had been trained in Guy's Hospital wards, but this he would declare—that at no time in the history of the hospital had it and those connected with the institution been doing a greater work in the cause of humanity and science and civilisation than at present. With regard to the future, they desired that Guy's should take the precedence of every hospital in the world, and they looked to those who had served in the wards and done their duty to the hospital in the past, to provide that one miserable thing, without which they could neither exist nor look forward—namely, money. They knew that so long as all connected with the hospital did their duty they would be supported by the public. Mr. French proposed the health of Dr. Taylor, who briefly replied. Mr. Cosmo Bonsor said that they could not allow Dr. L. E. Shaw to pass from his position as dean of the Medical School without expressing on this occasion their gratitude to him for his past work and their fervent hope that he might have health and happiness in his retirement of *otium cum dignitate*. During all the years that he had been Dean, on these occasions he had been extraordinarily mysterious, and had apparently passed on that tradition to his successor, Dr. J. Fawcett, who would not give him (Mr. Bonsor) the slightest information as to "entry day." Without knowing

in the least what the "entry" was likely to be, he thought they might congratulate Dr. Shaw on what he had done for the school in the past. They were all grateful to him for his work, they would drink his health, and at the same time they would hope that his mantle had fallen successfully on Dr. Fawcett. Dr. Shaw responded, and the singing of "Auld Lang Syne" brought to a close a very pleasant and successful evening.

**London Hospital.**—The 117th session was opened on Oct. 1st with the usual old students' dinner, which was held in the library of the college, Dr. Frederick Daly being in the chair. 100 old students sat down to dinner. Dr. Daly, in congratulating the old students on the prosperity of the old hospital and college, called attention to the enormous improvements which were now taking place, especially the addition of the new pathological block, outpatient department, isolation block, and operating-theatres. He said that a great deal of the work was now complete, and added that it was probably without precedent that such an enormous amount of work should have been carried on without a single bed being closed, so that the study of medicine and the students' career had not been checked for a single hour. He also called attention to the large number of old students who had been out to the front, particularly alluding to the honours that had fallen to the College by Sir Frederick Treves receiving knighthood and Captain Neville R. Howse (from Australia) the Victoria Cross. Mr. M. Brownfield and Dr. J. Edmunds, old London students who qualified in 1854, said that they perhaps could speak with greater authority on the London Hospital Medical College than anyone else present. Throughout their lives they had felt thankful for the education they had received at their old hospital and for the enormous experience in practical work that they had there gained. Mr. T. H. Openshaw, and others who had recently returned from South Africa, spoke also of the practical work done by London Hospital men at the front. Mr. J. A. Hosker, late mayor of Bournemouth, and other speakers bore tribute to the excellent opportunities afforded by their old hospital and college.

**St. Thomas's Hospital.**—The St. Thomas's old students' dinner was held at the Whitehall Rooms of the Hôtel Métropole on Oct. 2nd. Mr. H. H. Clutton was in the chair and was supported on either hand by General Sir Ian Hamilton and General Sir Reginald Wingate, the Sirdar. This year a new departure was made in order to give the old students an opportunity of talking with their former companions, for which purpose a conversation was held in the reception-room after dinner. After drinking the toast of "The King and the Royal Family," followed by that of "Success to St. Thomas's Hospital," which latter was replied to by Mr. T. G. Wainwright (the treasurer) and Dr. H. G. Turney (the dean), Dr. S. J. Sharkey proposed the health of the Chairman, who in his reply proposed that of the secretaries, which was responded to by Mr. E. M. Corner. There were 150 people present and all adjourned to the reception-room after dinner and there ended one of the most pleasant and successful meetings of the St. Thomas's old students. The great success of the conversation will, it is hoped, lead to still further developments next year.

**University College Hospital.**—The past and present students of University College Hospital held their annual dinner at the Hotel Cecil on Oct. 1st. The chair was occupied by Sir Richard Douglas Powell who proposed the toast of the evening, "Success to University College Medical School," to which the Dean of the medical school, Professor John Rose Bradford, replied. Amongst the other speakers were Dr. F. Roberts and Sir John Williams. The dinner was well attended, over 120 guests being present.

## ASYLUM REPORTS.

**Surrey County Asylum, Brookwood (Annual Report for 1900).**—The average number of patients resident during the year was 1033, comprising 421 males and 612 females. During the year 285 patients were admitted, 133 being males and 152 females. Of these 239 were first admissions. Mr. James E. Barton, the medical superintendent, states in his report that a female patient admitted from the Richmond Hospital developed scarlet fever five days afterwards. Three other patients and a nurse were attacked and had to be removed to the Cottage Hospital. The admissions were

generally found to be "of a bad class as regards recovery. 71 had suffered from previous attacks, and in 53 the insanity was of more than a year's duration." A female patient who was admitted pregnant was confined of a child. Of the causes of insanity in the admissions, worry, overwork, and adverse circumstances accounted for nearly 28 per cent. Alcoholic intemperance and previous attacks were the causes in 35 and 51 cases respectively. "In 18 instances the mental disorder followed an attack of influenza. 14 general paralytics were admitted, all of whom were males, and the majority of these came from the parishes situated on the London side of the county." "There is no doubt," adds Mr. Barton, "that general paralysis has been diminishing in frequency in the rural districts for some years past, and in the female sex it appears to be approaching the vanishing point, only six cases having been admitted during the last five years." The number of patients discharged as recovered during the year was 89—viz., 50 males and 39 females, or 8.6 per cent. of the average number resident. The deaths during the year amounted to 101, including 40 males and 61 females, or 9.77 per cent. as calculated on the same basis. 11 patients died within one month of admission. Of the deaths one was due to myxœdema, two were due to cancer of the liver, three to Bright's disease, seven each to epilepsy and cardiac disease, eight to cerebral hæmorrhage, nine to pneumonia, 10 to organic brain disease, 11 to senile decay, 13 to general paralysis, 16 to phthisis and other forms of tuberculosis, and the rest to other causes. An inquest was held on the body of a male patient who committed suicide by strangulation. "This patient was the subject of melancholia. .... He was found suffering with an ischio-rectal abscess which was opened. .... On the following day he was found by the charge attendant on the floor with one of the triangular bandages which had supported the surgical dressing tied tightly round his throat." Only four casualties to patients occurred during the year, three of these being fractures of bones and one a dislocation, all due to accidental falls. A complete fire and domestic service has been laid on to the Cottage Hospital from the water company's main, and the outlet of the asylum drain has been connected with the district council's main sewer so that any excess of sewage beyond what can be beneficially utilised can be turned into the Woking sewer. The erection of additional wards at a cost of £87,000 to accommodate 350 patients was commenced in August, 1900. An outbreak of swine fever occurred at the farm in April, necessitating the destruction of the whole herd. The Commissioners in Lunacy state in their report that the day-rooms were bright and cheerful, the dormitories and bedding neat and clean, and the case-books and post-mortem records carefully kept. They commend the recent addition of another medical officer to the staff, and hope that pathological work will now be undertaken.

**Durham County Asylum (Annual Report for 1900).**—The average number of patients resident during the year was 1415, comprising 736 males and 679 females. During the year 330 patients were admitted, of whom 165 were males and 165 females. Of these patients 253—viz., 135 males and 118 females—were first admissions. Dr. W. St. John Skeen, the medical superintendent, states in his report that "the admissions were of the usual type and still show a large percentage of aged people; 26 patients were over 60 years of age, of whom four were over 75 years; 72 were admitted in a feeble state, and most of them died soon after admission." Among the admissions were 27 cases of general paralysis. The number of patients discharged as recovered during the year amounted to 149, or 10.5 per cent. of the average number resident. Of 818 patients discharged as recovered during the five years 1896 to 1900 inclusive, 124 have relapsed during the same period. The deaths during the year amounted to 165—viz., 94 males and 71 females, or 11.6 per cent. of the average number resident. Of the deaths, one was due to asphyxia by choking, five were due to cerebral hæmorrhage, eight to epilepsy, 12 to influenza and its complications, 12 to congestion of the lungs, 15 to pneumonia, 29 to general paralysis, 30 to cardiac disease, 34 to phthisis and other forms of tuberculosis, and the rest to other causes. Four cases occurred during the year of serious injuries in the form of fractures sustained by patients accidentally or by being pushed down by other patients, and in three of the cases satisfactory recoveries were obtained. During the year two female patients gave birth to children, in one case a boy and in the other a girl, but in neither case is the mother anticipated to make a satisfactory mental

recovery. The asylum committee state in their report that having regard to the requirements expressed from time to time by the Commissioners in Lunacy of provision at the asylum for the isolation of infectious diseases, the committee have decided to erect a small detached isolation hospital for the purpose. Electric lighting is now in operation throughout the building. The farm has continued to yield abundance of milk, meat, and vegetables, and the whole of the live stock, with the exception of two cows which had to be destroyed, were in good health. The Commissioners in Lunacy state in their report that the wards and dormitories were comfortable, fresh, and clean. They state that Dr. R. Smith, the late medical superintendent, after a long and faithful service of 44 years, has retired on a pension and has been succeeded by Dr. Sken, the senior assistant medical officer. They regret to find that it is proposed to reduce the medical staff by abolishing the post of pathologist. "This we consider a retrograde step and hope the committee can see their way to reconsidering the matter." They also state that "the insufficiency of the medical staff of late no doubt accounts for the [medical] case-books being considerably in arrears." At a more recent visit (Feb. 15th, 1901) the Commissioners in Lunacy refer to Newton Hall, an annexe of the asylum prepared for the accommodation of 52 male patients from the county asylums, all of whom are of the chronic quiet class, and who appear very healthy and contented in their new surroundings. Three assistant medical officers "are now on duty, and the case-books duly entered up to date."

*Royal Edinburgh Asylum (Annual Report for 1900).*—The average number of patients resident during the year was 940, comprising 482 males and 458 females. During the year 472 patients were admitted, of whom 248 were males and 224 were females. Of these 117—viz., 55 males and 62 females—were not first admissions. Dr. T. S. Clouston, the medical superintendent, states in his report that the year 1900 has been a record year for admissions, the number of admissions being 38 over the average of the preceding five years. This increase has been entirely in pauper cases, so that scarcely enough room could be found for private cases. A number of chronic insane pauper patients were boarded out during 1899 in other asylums with the view of providing room in the West House of the Edinburgh Asylum for recent and urgent private cases from Edinburgh. But this anticipation was not fulfilled owing to the exceptional increase of pauper patients among the admissions, chiefly from Edinburgh. As regards the cause of such an increase of pauper patients Dr. Clouston thinks that the excessive use of alcoholic liquors has to a large extent been the main factor. "We had, as a matter of fact, 115 cases, or about a quarter of our whole number of admissions, in whom drink was assigned as either the sole or as a contributory cause of the disease. If the admissions of men alone are looked at, 81, or about one-third of them, were alcoholic cases. I have never had experience of anything approaching this before, and I should fail in my duty if, seeing more of the terrible effect of excessive alcoholic drinking in destroying honour and reason and self-control than almost anyone else in Scotland, I did not strongly draw attention to a fact so disgraceful to us as a community. .... It is certain that for every man in whom excessive drinking causes absolute insanity there are 20 in whom it injures the brain, blunts the moral sense, and lessens the capacity for work. .... When in any community there is a large class to whom prosperity always means excessive indulgence in drink in defiance of natural and moral law it means that a higher sort of education is needed or that degeneration has set in. .... A true conception of liberty does not necessarily imply liberty for a man to drink himself to death if he can afford to do so at his own expense or the right to render himself a burden on other people and a source of degradation and danger to the community. .... Our recent Inebriates Act is almost a dead letter and Lord Peel's report remains as yet an interesting subject of academic discussion. .... Convictions for being drunk and incapable steadily increase in Scotland; my alcoholic lunatics have risen from an average of 15½ per cent. in the years 1874-1888 to 21½ per cent. in 1889-1898, to 22½ per cent. in 1899, and now to 24½ per cent. in 1900 .... and yet the politician cries *non possumus*. .... The national drink-bill steadily goes up and the national degeneration progresses. I am convinced that we shall have a big reckoning to pay some day. .... A consumptive race might conceivably be cured in two generations, or even in one by good conditions. I do not believe a

drink-sodden race could be fully cured in a hundred years. .... We can, I think, put down most of our 115 alcoholics of the year as being preventable and we can, if the current views of its causation are true, put down almost all our 49 general paralytics as in that list." Many of the patients admitted were suicidal and some were dangerous to others. During the year 165 patients were discharged as recovered, or 17·5 per cent. of the average number resident. The deaths during the year amounted to 99, or 10·5 per cent. as calculated on the same basis. Of the deaths two were due to Bright's disease, five to pneumonia, 10 to cardiac disease, 14 to phthisis and other forms of tuberculosis, 17 to general paralysis, 19 to senile decay, and the rest to other causes. Concerning the high mortality from phthisis Dr. Clouston observes that "many of the patients are very weak indeed on admission. .... They are liable therefore in an undue degree to fall victims to the tubercle bacillus." The general health of the inmates has been good with the exception of a slight outbreak of scarlet fever in Craig House from infected milk, one sporadic case of typhoid fever in the West House, and one case of small-pox occurring in a patient who had come on a South American steamer. The Commissioners in Lunacy state in their report that the asylum throughout is maintained in excellent order and that the medical case-books and registers are well kept, full accounts being written of the treatment and progress of the various patients under care. The Board of Managers state in their report that there is little prospect of the new asylum for the Edinburgh district being ready for occupation in February, 1902, as was at first calculated, and they "cannot without anxiety contemplate the prospect of having to find accommodation for the ever-increasing number of paupers."

## THE FIFTH INTERNATIONAL CONGRESS OF PHYSIOLOGISTS.

HELD AT TURIN, SEPT. 17TH-21ST, 1901.

The following are some further notes of communications made to the above Congress:—

### *The Results of Trephining the Cranium of Young Animals.*

M. JEAN DEMOOR (Brussels) contributed a paper on the above subject. He said that Danilewsky had found that trephining the cranium of young dogs was followed at a later stage by (1) arrest of development of the limb corresponding to the region trephined; and (2) the supervention of epileptiform convulsions followed by death, generally at the age of six months. M. Demon was able to corroborate the latter result but not the former in its entirety. The wasting was general. The animals developed normally during the months prior to the convulsions, but at the post-mortem examination showed no emaciation or other phenomena indicative of the region trephined. Experiments on rabbits gave similar results. Histological examination of the brains revealed a very marked moniliform condition of the cortical nerve-cells. Stained by the method of Golgi the enlargements were darkly coloured and the intervening strands were pale. This condition was the result of the strong cortical excitation which accompanied the epileptiform convulsions in which the animals died. If killed during the period of wasting the nerve-cell processes were smooth. A marked degree of chromolysis was also seen in the nerve-cells accompanied by a great poverty of chromatic substance which the author regarded as characteristic of the nerve-cells of trephined animals. There was no neuro-phagocytosis present except in one animal when death came on very slowly preceded by a state of imbecility.

### *Attempts to Educate a Pigeon devoid of Cerebral Hemispheres.*

Dr. Z. TREVES and Dr. A. AGAZZOTTI (Turin) had found that after removal of the cerebral hemispheres the animal remained motionless for several days. Then slight spontaneous movements were made and later a few steps. If placed on a small stage the bird dropped off on reaching the edge, but afterwards learned to advance with caution and remained upon it. This indicated some power of perceiving and remembering impressions. The perch was a low platform a few inches square, placed within a fume chamber in the laboratory; when thus far recovered the bird was dropped near its stage and encouraged to return, aid being given at

first. Then the distance was gradually increased about two inches at a time till ultimately at the end of five months it was able to fly back and to hop up upon its perch from a distance of eight metres. Up to this time it was impossible to induce it to fly in a direction away from the chamber or to fly down from a higher to a lower level, but later both these movements were accomplished. At Easter it was taken for a fortnight to Modena, where other exercises were taught, and on returning to Turin it at once found its way back to its old perch when set free in the room. Its acquirements gradually increased, but it never spontaneously left its support or made any attempt to peck at food. In July it was again taken to Modena and attempts were made to educate it to discern colours, but without noticeable success. Unfortunately, the pigeon died in August, nine months after the cerebral hemispheres were removed. A control pigeon, operated upon at the same time, acquired only a very limited power of movement, but was never able to fly or to return to its perch when only placed a few inches distant.

#### *The Effects of Nicotine on Nerve Cells and Nerve Endings.*

Professor J. N. LANGLEY, F.R.S. (Cambridge), contributed a paper on the above subject. Nicotine solution applied to a ganglion of the sympathetic prevented, as Professor Langley had previously shown, the passage of nerve impulses from the pre-ganglionic to the post-ganglionic nerve-fibre. There was doubt whether the alkaloid in this instance paralysed the nerve-cells or the nerve terminations of pre-ganglionic fibres around these cells. To settle the point the pre-ganglionic trunk was divided and time for degeneration of its fibres allowed. Nicotine applied locally to the ganglion now called forth its normal stimulation effects, so that the alkaloid must have had a direct stimulating effect upon the nerve-cells. Furthermore, nicotine when applied to a sympathetic ganglion caused only a localised erection of skin-hairs in the region supplied by the ganglion. This showed that it could have excited pre-ganglionic nerve-endings, otherwise the movement of hairs should have been much more general. On the other hand, nicotine had no exciting effect on spinal ganglia, nor did it seem to paralyse them, since it did not prevent the passage of nerve-impulses through the bipolar ganglionic cells of the skate. Applied to the spinal cord of this animal the alkaloid caused violent muscular twitchings or tetanus localised in the muscles supplied from the segment. On continued application this effect ceased, but even then muscular movement could be obtained by stimulating a posterior root. Transmission of impulses through the nerve-cells in this case was therefore not destroyed. The foregoing experiments illustrated three different kinds of response on the part of different nerve-cells to one and the same physiological reagent. Other observations also went to show that "the physiological behaviour of the different neurons which make up the nervous system of the body" under similar conditions is different. Professor Langley gave a demonstration of the stimulating action of nicotine on the superior cervical ganglion.

#### *Vascular Dilatation from Excitation of the Peripheral Segment of the Divided Posterior Spinal Nerve Root.*

Mr. W. M. BAYLISS (London) stated that he had found, in confirmation of the statements of Stricker, Morat, and others, that the posterior roots of the fifth, sixth, and seventh lumbar and the first sacral nerves contained fibres the excitation of which after separation from the spinal cord caused vascular dilatation in the hind limb. The effect was not abolished by morphine or other anæsthetic. The fibres passed directly into the lumbo-sacral plexus without entering the abdominal sympathetic. They did not degenerate when severed between the cord and the posterior root ganglion, and hence were not efferent from the spinal cord. They degenerated when the ganglion was extirpated and therefore had their trophic centres in the ganglion. They conformed in this respect to ordinary sensory afferent fibres. The name "antidromic" was suggested by Mr. Bayliss for the process by which such nerve fibres conveyed impulses in a direction contrary to that assumed by Majendie's law. No other vaso-dilator fibres passed to the hind limb, hence any reflex excitation of limb vaso-dilators must be "antidromic" in nature. This applied even to vaso-dilatation in the limb caused by excitation of the depressor nerve or central end of the vagus, also to the Lovin reflex produced by excitation of the anterior crural nerve. The corresponding vaso-dilators of the fore limb were situated in the posterior roots of the sixth, seventh, and eighth cervical and first thoracic nerves.

No effects of a like nature had up to the present been obtained with the kidney or intestine.

#### *Muscular Tremors in Parkinson's Disease.*

Dr. C. NEGRO and Dr. Z. TREVES brought forward a paper on Muscular Tremors in Parkinson's Disease. Dr. Negro had observed twitches or tremors of muscles in patients suffering from Parkinson's disease which he regarded as characteristic of the affection. They were especially marked in the triceps brachialis, when both voluntary and passive movements of the elbow-joint were carried out and particularly when passing from a state of moderate extension to that of flexion. In conjunction with Dr. Treves he had made a more accurate study of their nature. The method of recording them was a plethysmographic one. Von Kries, Schäfer, and others had recorded simple twitches superimposed on the larger contractions of voluntary tetanus. The strength or prominence of these was not uniform, but they showed a frequency as a rule of from 10 to 12 per second. They were not much influenced by fatigue or by the degree of resistance opposed to the contractions. Heavy weights, however, tended to reduce the rate to eight or nine per second. Schäfer had found that similar elementary twitches were present with the contractions caused by excitation of the cerebral cortex, no matter what the rate of stimulation employed. The regulation of their rhythm was therefore a function of the nerve-cell. The tremors of Parkinson's disease corresponded in every way except rate of occurrence with the foregoing observations. Their average rapidity was from 6.4 to 5.6 per second. Hence it must be inferred that in this affection the nerve-cells were unable to emit a series of impulses sufficiently rapid to produce the relatively smooth tetanic voluntary contraction of health. The pathology of the disease lay, therefore, in an altered condition of cerebral nerve cells. This explanation would also account for the great muscular weakness which Dr. Negro and Dr. Treves observed in the affection. It was hoped that their research would constitute a basis for further investigations into the nature of the pathological alteration underlying the disease. Figures were shown recording the tremors in one case. They were small undulations best marked during the phases of extension on the larger waves which represent variations of volume of the forearm.

## Looking Back.

FROM

THE LANCET, SUNDAY, OCTOBER 19, 1823.

*Chemical Discovery.*—M. Dobereiner, Professor of Chemistry in the University of Jena, gives an account of a discovery of the greatest importance. By a series of entirely new experiments, he has ascertained that platina, the heaviest of all elementary substances, when reduced into very fine particles, produces, by simple contact with hydrogen gas (the lightest of elementary substances), an electrical or dynamic combination, which, if brought into contact with hydrogen gas, or with atmospheric air, instantly dissolves itself, yielding fire and water. To prove this important fact by a brilliant experiment, M. Dobereiner makes hydrogen pass from a reservoir, by a capillary tube, curved below, upon pure platina in powder, which is confined in a glass tunnel, hermetically sealed at the point, so that the gas mingles with the atmospheric air before it touches the platina. The moment that the current of gas reaches the surface of the platina, the powder of that metal becomes red and burning, and this phenomenon continues as long as the stream of gas is directed upon it. This fine discovery will open a new field for physical and chemical researches.

*Caleb Quot'em Eclipsed.*—In the village of Harrington, between Evesham and Alcester, a sign-post, exhibited by the side of a barber's pole, thus announces the multifarious occupations, avocations and qualifications, of the industrious and indefatigable inmate.—James Tarrant, joiner, cabinet maker and builder, bricklayer and plasterer, repairs all kinds of machinery, keeps a journeyman carpenter to do all sorts of blacksmith's work, hangs church bells, pig killer, rings pigs and spays, bellows mender, tooth drawer and hair dresser, well sinker and thatcher, jobbing gardener.—N.B. Gamekeeper to the manor of Norton and Linchwick.

## Public Health and Poor Law.

### LOCAL GOVERNMENT BOARD.

#### ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Nottingham Urban District.*—Enteric fever was very prevalent in Nottingham during 1900 and Dr. P. Boobyer makes the defects of the conservancy system responsible for it. The prevalence would appear to be confined to certain districts. Special steel pails—as contrasted with wooden pails commonly in use—are employed for the excreta of all patients who are treated at their own homes, but, as Dr. Boobyer observes, a case only comes under preventive measures when its nature is sufficiently apparent to enable the medical attendant to notify, and by this time all the damage may be done. It is thought that the wooden pails absorb the excreta and give out infected dust. The influence of excrement disposal on, or rather its association with, the prevalence of enteric fever is well shown from the fact that with pail-closets one case occurred in every 92 houses, with midden-privies one in every 20, and with water-closets one in every 407. Dr. Boobyer has also observed that there is a concentration of cases to the leeward of the refuse heaps, an association which has been observed for the last three years.

*Portsmouth Urban District.*—Dr. A. Mearns Fraser reports that an effort is being made in Portsmouth to erect a sanatorium for tuberculous patients by means of voluntary subscriptions. He thinks that if this praiseworthy attempt fails in its object the town council, as the sanitary authority, should take up the matter and carry it out well. As he observes, large sums are being expended annually upon the prevention of enteric fever, scarlet fever, and diphtheria, whereas practically nothing is being expended upon the direct control of tuberculosis, and this notwithstanding the fact that the three diseases just mentioned exacted a death-toll in Portsmouth in 1900 only a little in excess of half that caused by the tubercle bacillus. There were no fewer than 1083 cases of enteric fever notified in Portsmouth last year, but the fatality-rate (8.49 per cent.) was fortunately not high. Dr. Fraser is unable to account for the prevalence of the disease, but its main incidence seems to have been on the poorer and less sanitary portions of the town.

*Bromsgrove Urban District.*—Dr. H. Cameron Kidd has in his estimate of the population of this district come very near to the census figures, the former being 8500 and the latter 8416. Dr. Kidd took the inhabited dwellings in the district as the basis of his calculations and he has every reason to be gratified with the result. Bromsgrove is doing good work in the matter of the control of tuberculosis, and it is encouraging to find so small a district as this emulating the practices of our large towns in this particular. Unfortunately the neighbouring sanitary authorities are not equally alert, and a proposal from Bromsgrove that there should be combination for the purpose of appointing a veterinary inspector did not receive adequate support. Dr. Kidd has, however, been able to induce his district council to adopt the scheme which is in operation at Ludlow under the advice of Dr. C. B. Cranstoun, the medical officer of health. Samples of milk from each dairy in the town are, after due notice, examined for tubercle bacilli, and if such bacilli are found the dairyman is summoned for selling "unsound milk," and ordered to stop the supply until it is proved to be pure. We presume that this means until no tubercle bacilli are to be detected therein. Moreover, the tuberculin test is applied to all cows supplying the dairy. This is very satisfactory, and Dr. Kidd is to be congratulated on having brought the scheme into operation.

*St. Helens Urban District.*—Dr. F. Drew Harris furnishes in his current annual report an interesting detailed account of the infant milk depot at St. Helens which has been carried on after the fashion of the original depot at Fécamp in Normandy. The subject is of considerable interest at the present moment owing to the discussion which has recently taken place in our columns upon the merits or demerits of boiled milk. A small six-roomed house was procured in a convenient position in St. Helens, and the several rooms were appropriated to one or another purpose connected with the scheme. In one room are contained the sterilisers and the bottle-washing machine, and in another

the baskets containing the supplies of bottled milk for each customer are stored. In another room the babies are weighed from time to time. The sterilised humanised milk for the infants is prepared by means of the dilution of, and the addition of cream and sugar to, good cow's milk. The milk is then placed in small stoppered bottles of some five ounces capacity, the stoppers are closed and the bottles are placed in the steriliser. By an ingenious device the steam is subjected to slight pressure by means of which its temperature is increased by about 2° C. When the thermometer registers 102° C. the time is noted and the bottles are kept at that temperature for 45 minutes, the whole operation lasting, it appears, from three to three and a half hours. We are assured that by this means the milk does not possess anything approaching a "boiled" taste and that such milk has been kept in the closed bottles for more than a month. When the heating process is ended the fire is raked out and the bottles are allowed to cool. They are then taken out and placed in baskets each of which holds nine bottles—i.e., six feeds for the day and three for the night. The quantity of the milk is adjusted according to the age of the child. Before use each bottle is placed in a little hot water, the stopper is removed, and a teat is fitted to the bottle direct. Every Wednesday the babies are brought to be inspected and weighed and the records are entered in a book. The number of children on the books has steadily increased and in August, 1900, over 140 were being fed. As yet it is difficult, Dr. Harris tells us, to furnish reliable statistics as to the results of the method, but there is evidence pointing to the conclusion that the infantile death-rate has been very markedly reduced thereby: indeed, the saving of life would appear to be about 86 per 1000. It seems, too, that during the hot weather of August many cases were brought to the depot in the last stages of diarrhoea and obtained the greatest benefit from the humanised milk. Dr. Harris also supplies his readers with the figures for Fécamp which show excellent results from the system. A depot has also been opened at Havre, and here, too, the results seem very promising. In England, Liverpool, Dukinfield, and Ashton have already started depôts, and in Belfast one is in course of construction.

*Bath Urban District.*—The Bath Town Council have decided to supply diphtheria antitoxin gratuitously to all those who cannot afford to purchase it, and this proviso will, we expect, be found in practice to have a wide application. Small tubes containing 800 Ehrlich-Behring immunity units are also provided for persons who have been exposed to infection. As Dr. W. H. Symons remarks, the prevention of one case of diphtheria which would be treated at the isolation hospital at the public expense would more than cover the cost of antitoxin for many years. The Bath Town Council have also a supply of plague serum and vaccine ready for emergency. These are praiseworthy provisions, and we are led to reflect as to how many sanitary authorities in this country are equally as ready as Bath in this sense. The voluntary notification of phthisis is in force in Bath and Dr. Symons has apparently been endeavouring to persuade the Great Western Railway Company to take action to prevent infection from spreading through the agency of railway carriages.

*Bedford County District.*—Dr. George Newman, in his annual volume, which summarises the reports of the district medical officers of health, devotes a small section to "Proceedings of the County Council Relating to Public Health." Such proceedings have not, we gather, unduly taxed the time of the Bedfordshire county councillors. Their total exertions in this sense seem to have taken the form of resolutions respecting the Bedford sewage farm, the distribution of communications with respect to the provision of diphtheria antitoxin by district councils, and as to the prevention of phthisis. Action was also taken in reference to the Biggleswade water-supply, and the medical officer of health was instructed to report upon the isolation accommodation of the county. These actions, however, although few in number, are steps in the right direction.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6556 births and 3498 deaths were registered during the week ending Oct. 12th. The annual rate of mortality in these towns, which had declined from 21.6 to 15.6 per 1000 in the seven preceding

weeks, rose again to 15.9 per 1000 last week. In London the death-rate was 15.0 per 1000, while it averaged 16.5 in the 32 large provincial towns. The lowest death-rates in these towns were 9.3 in Derby, 9.7 in Croydon, 11.6 in Swansea, 12.0 in Cardiff, 12.6 in Plymouth, and 12.7 in Birkenhead; the highest rates were 19.6 in Hull, 20.8 in Manchester, 21.7 in Salford, and 22.5 in Newcastle. The 3498 deaths in these towns last week included 485 which were referred to the principal zymotic diseases, against 732, 634, and 525 in the three preceding weeks; of these, 217 resulted from diarrhoeal diseases, 93 from diphtheria, 55 from "fever" (principally enteric), 51 from scarlet fever, 34 from measles, 32 from whooping-cough, and three from small-pox. The lowest death-rates from these diseases were recorded in Derby, Birkenhead, Huddersfield, Halifax, and Bradford; and the highest rates in West Ham, Salford, Sheffield, and Hull. The greatest proportional mortality from scarlet fever occurred in Swansea, Preston, and Halifax; from whooping-cough in Newcastle; from "fever" in West Ham and Portsmouth; and from diarrhoeal diseases in West Ham, Wolverhampton, Salford, Hull, Sheffield, and Gateshead. The mortality from measles showed no marked excess in any of the large towns. The 93 deaths from diphtheria in these towns included 54 in London, five in West Ham, five in Leicester, and four in Liverpool. Three fatal cases of small-pox were registered in London, but not one in any of the 32 large provincial towns; the number of small-pox patients under treatment in the Metropolitan Asylums hospitals at the end of the week was 175, against numbers which had increased from 13 to 169 on the eight preceding Saturdays; 37 new cases were admitted during the week, against 37, 44, and 51 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had increased from 2994 to 3159 at the end of the five preceding weeks, had further risen to 3280 on Saturday last; 422 new cases were admitted during the week, against 427, 460, and 426 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 124, 137, and 132 in the three preceding weeks, increased again last week to 186, but were 55 below the corrected average. The causes of 39, or 1.1 per cent., of the deaths in the 33 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Salford, Bradford, Hull, and in 16 other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Manchester, Halifax, Sheffield, and Sunderland.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 17.8 to 14.5 per 1000 in the five preceding weeks, rose again to 16.1 during the week ending Oct. 12th, and showed an excess of 0.2 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 6.2 in Perth and 10.4 in Paisley to 17.7 in Dundee and 23.6 in Greenock. The 513 deaths in these towns included 32 which were referred to diarrhoea, seven to scarlet fever, six to measles, six to diphtheria, six to "fever," and five to whooping-cough. In all, 62 deaths resulted from these principal zymotic diseases last week, against 73 and 82 in the two preceding weeks. These 62 deaths were equal to an annual rate of 1.9 per 1000, which was 0.3 below the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhoea, which had been 42 in each of the two preceding weeks, declined last week to 32, of which 18 occurred in Glasgow, four in Edinburgh, three in Dundee, three in Leith, and two in Aberdeen. The deaths from scarlet fever, which had been two, four, and seven in the three preceding weeks, were again seven last week, and included four in Greenock and two in Glasgow. The fatal cases of measles, which had been five, 12, and 14 in the three preceding weeks, declined again last week to six, of which five were registered in Glasgow. The six deaths from diphtheria corresponded with the number in the preceding week, and included three in Edinburgh and two in Glasgow. The fatal cases of whooping-cough, which had been seven in each of the two preceding weeks, declined last week to five, of which three occurred in Edinburgh. The deaths referred to different forms of "fever," which had been six, seven, and six in the three preceding weeks, were again six last week

and included four in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 101 and 77 in the two preceding weeks, further declined last week to 75, and showed a decline of 29 from the number in the corresponding period of last year. The causes of 16, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23.4, 17.8, and 19.9 per 1000 in the three preceding weeks, declined again to 19.7 during the week ending Oct. 12th. During the past four weeks the death-rate has averaged 20.2 per 1000, the rates during the same period being 15.1 in London and 15.6 in Edinburgh. The 142 deaths belonging to Dublin registered during the week under notice were only slightly below the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 30, 17, and 20 in the three preceding weeks; of these, 14 resulted from diarrhoea, six from "fever," and one from whooping-cough. These 21 deaths were equal to an annual rate of 2.9 per 1000, the zymotic death-rates during the same period being 1.9 in London and 1.8 in Edinburgh. The fatal cases of diarrhoea, which had been 20, 11, and 9 in the three preceding weeks, rose again last week to 14. The deaths referred to different kinds of "fever," which had been three, three, and eight in the three preceding weeks, declined again to six last week. The 142 deaths in Dublin last week included 36 of children under one year of age and 29 of persons aged upwards of 60 years; the deaths of infants showed a slight increase, while those of elderly persons were considerably below the number in the preceding week. Six inquest cases and five deaths from violence were registered; and 39, or more than one-fourth, of the deaths occurred in public institutions. The causes of 14, or nearly 10 per cent., of the deaths in Dublin last week were not certified.

### THE SERVICES.

#### ROYAL NAVY MEDICAL SERVICE.

The following appointments are announced:—Staff Surgeon A. J. Pickthorn to the *President* for three months' hospital duty. Surgeons: H. W. G. Green to the *Majestic*; E. Sutton to Plymouth Hospital; R. B. Scribner to the *Shearwater*; and M. L. M. Vaudin to the *Wildfire* for the *Immortalité* and Naval Barracks.

#### ROYAL ARMY MEDICAL CORPS.

Major Henry James McLaughlin to be Lieutenant-Colonel. Dated July 27th, 1901. Lieutenant Robert Longfield Davies resigns his commission. Dated Oct. 12th, 1901. Civil Surgeon Stafford Adye-Curran to be Lieutenant. Dated July 26th, 1901. Major H. M. Sloggett is posted to the Station Hospital, Western Heights, Dover, for temporary duty. Surgeon-Major J. Mill, A.M.R., has assumed temporary medical charge of troops, Station Hospital, &c., Leith Fort. Lieutenant-Colonel H. Charlesworth is posted to Portsmouth for general duty. Lieutenant C. Thompson has joined at Aldershot and is posted to the Depot. Captain H. D. Mason is appointed Adjutant of the Manchester Companies of the Volunteer Medical Staff Corps. Major W. A. Morris has joined at Aldershot, and is posted to the Cambridge Hospital for duty.

#### VOLUNTEER CORPS.

*Artillery*: 1st Cardigan (Western Division, Royal Garrison Artillery): Abraham Thomas to be Surgeon-Lieutenant. *Rifle*: 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: John Griffiths to be Surgeon-Lieutenant.

#### VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies:—Donald James MacKintosh to be Surgeon-Lieutenant.

#### SOUTH AFRICAN WAR NOTES.

The following have been discharged from hospital to duty:—Major J. H. Brannigan, R.A.M.C., Colonel J. Lane Notter, R.A.M.C., Captain J. Grech, R.A.M.C., and Civil Surgeon Philip William James.

Lieutenant-Colonel J. G. MacNeece, R.A.M.C., Captain G. S. McLoughlin, R.A.M.C., Lieutenant J. W. H. Houghton, R.A.M.C., and Civil Surgeons R. H. Browne

and E. H. Ridley left Port Natal for England on Oct. 12th in the *Orcana*.

Surgeon-Lieutenant-Colonel C. R. Kilkelly, C.M.G., Grenadier Guards, Principal Medical Officer of the Imperial Yeomanry Hospital, in his returns of the Elandsfontein Hospital states that on Sept. 20th there remained in that hospital eight officers and 119 non-commissioned officers and men, the total admissions at that date having been 257 patients.

Mr. Douglas Drew, F.R.C.S., consulting surgeon of the Imperial Yeomanry Hospital at Pretoria, together with several nursing sisters and other time-expired members of the staff, have now returned to this country.

#### DEATHS IN THE SERVICES.

Captain Frederick John Gaine, R.A.M.C., on Oct. 8th, aged 31 years. He joined the Army in 1897 and served in the Nile Expedition in 1898 and the expedition to Khartoum (Egyptian medal with clasp and British medal).

The appointment of assistant surgeon to the Royal Military College, Sandhurst, will be vacant in December, Lieutenant-Colonel F. Gillespie, A.M.S., having sent in his resignation.

## Correspondence.

"Audi alteram partem."

### NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—I am reminded by your annotation in THE LANCET of Oct. 12th, p. 987, on "Medical Officers of Health and Diagnosis," of a letter which I wrote to you almost exactly a year ago<sup>1</sup> *apropos* of "The Notification of Plague," the suggestions of which you did not see your way to accept at that time, but may possibly now come to see in a different light. I gave it as the result of experience that the present forms of notification under the Act—i.e., of particular diseases named therein and presumed to be completely recognised *before* notification—tend to undue delay; and that "what is desirable in the public interest is the earliest possible communication to the sanitary authority not of a fully-formed diagnosis but of even a reasonable suspicion, founded on stateable facts, of infection." In the issue you have raised as regards Mr. A. Wynter Blyth's (academic) dictum "that the diagnosis of cases is no part of the duty of a medical officer of health," I am at one with you (only, if possible, more so!). It would be indeed a most perilous position were it to become accepted that a medical officer of health, with his larger experience and wider knowledge of the surroundings, could do nothing but sit still and wait till the identity of a doubtful case of acute disease had become perfectly plain to the possibly inexperienced, possibly prejudiced, mind of a junior who may very likely never have seen a like case before, and may without much blame, or at any rate without a clear notion of the mischief he is doing, linger over a diagnosis for a week or more, while the disease is all the while making havoc. In Dr. T. Colvin's case alluded to in my former letter 18 days of very acute disease elapsed before the diagnosis of plague was made, and it is even now very doubtful if the diagnosis would have been made at all, but for the happy accident of Dr. Colvin's having been then sent for, he being already familiar with the symptoms. Yet these symptoms were such as might very easily and certainly have suggested an infectious disease of some kind, not only to a medical man but to any ordinarily intelligent observer. I hold that no one in such cases as these—or, indeed, in any cases where the surroundings give rise to suspicion—can be exempted from the legal or moral responsibility of communicating the facts, or even his suspicions about them, to the authorities, and that it is the clear duty of the medical officer of health to encourage all such early information in the public interest (with or without a diagnosis); and further, to clear up the facts as well as he can, to correct the suspicions if necessary, and thus to make, or to assist in making, the diagnosis on which he is to take action. To do this amicably, courteously, and without giving offence

requires tact no doubt, and may not always be possible; but if the medical officer of health is not in a position to do this it may be taken as certain that nobody else will, and so doubtful cases of infectious disease must needs go on smouldering indefinitely, till they clear themselves up by reproducing themselves in forms more easily recognised, probably when too late. I hold that the Notification Acts should be amended so as to invite, rather than compel, notification even of suspicious cases of infection by anyone cognisant of the facts, and that the medical officer of health, as the neutral and impartial servant of the public, is the proper person to make the diagnosis in all cases admitting of reasonable doubt. Will you kindly read over again my letter aforesaid in the light of this new aspect of the case and give us once more your views upon it?

I am, Sirs, yours faithfully,

Edinburgh, Oct. 12th, 1901.

W. T. GAIRDNER.

P.S.—I had not access to the *Times* of Oct. 8th at the time of writing the above, but after a most careful perusal of the letters of Dr. David Roxburgh and Mr. Wynter Blyth on which your remarks are founded, I have no hesitation at all in giving my unqualified support (*valeat quantum*) to the contention of the former as against the latter. It is not without a sense of surprise (founded on my Scotch experience) that I read in the fourth and fifth paragraphs of Dr. Roxburgh's letter how grudgingly, and, as it were, unwillingly, the St. Marylebone authorities are accustomed to receive the notification of "doubtful" cases; for, as Dr. Roxburgh well says, it is obvious that the "doubtful" cases are the ones which create epidemics; and "medical men will not notify them if the authorities persist in refusing to share the responsibility, as they do in St. Marylebone, and probably elsewhere in London, but certainly not in Glasgow, where I (Dr. R.) was educated." I have only to add that from my own personal knowledge I can affirm that Dr. Roxburgh is well entitled to speak thus.

### "THE NEW CHIEF MEDICAL OFFICER FOR CAPE COLONY."

To the Editors of THE LANCET.

SIRS,—Some weeks ago I was surprised and pained to read in *Greater Britain* a very venomous and untruthful attack against my friend and late colleague, Dr. A. John Gregory. The statements made in that journal were absolutely devoid of any foundation whatever and such as would not be credited by any respectable medical man in South Africa. Had the matter rested there I should have advised my friend to ignore it entirely. Later, however, it came to my knowledge that Dr. Scholtz of Cape Town had brought forward a resolution at the Medical Council condemning the action of the Government in appointing Dr. Gregory to the post of medical officer of health for the Cape Colony, vacant by my recent resignation, and that Dr. Stevenson had not been ashamed to second it. The proposer and seconder alone supported the proposition and the other members were not sparing in expressing their opinion as to the nature of the resolution.

Up to this time I had not had any communication with Dr. Gregory on the subject, but I then asked his permission to refute the statements which had been published concerning him because he was debarred by his position from doing so himself. Dr. Gregory replied asking me to leave the matter alone. He said that the identity of the author of the statements was an open secret and that he attached no importance to the incident. Of course, I obeyed him. I should have continued to comply with my friend's request to mind my own business and to leave his alone had the matter rested there. But the thing takes a different aspect when it is published in a medical paper of acknowledged standing, such as THE LANCET, and I wish you to publish the facts as I know them and as I verily believe the author of the slanders in *Greater Britain* knew them when he made his communication.

Dr. A. John Gregory was first employed by the Cape Government to give professional advice and assistance in taking the last census. He did that work well and so successfully demonstrated to those then in power the necessity for employing a medical officer of health that it was decided to create the office. I have not the least doubt that Dr. Gregory would have been elected to the new appointment, which he already filled as acting medical officer, only

<sup>1</sup> THE LANCET, Oct. 13th, 1900, p. 1496.

pressure was brought to bear on the Ministry and I was selected. Had I known the strong claims Dr. Gregory had to the appointment I should certainly not have been a candidate, but I knew nothing about it until I had been appointed and had resigned my position at home. Many men in Dr. Gregory's place, disappointed at losing a post to which they had every reason to suppose they would be elected and having to submit to a consequent reduction of pay from £1000 to £600 per annum, would have set to work to prove to the Government that my election was a mistake. Dr. Gregory, however, is absolutely incapable of acting in such a way. I frankly explained to him that I had burned my boats and could not go back. He accepted the position with the best grace possible and, instead of an enemy ready to point out and rejoice at my many faults, I found a friend ever ready to assist me in all possible ways, whose experience of South Africa was invaluable to me, to whom the Colony with its many peculiarities was entirely new.

The statement that Dr. Gregory "seems to have spent the greater part of his time in the Colony not so much in acquiring a knowledge of sanitary matters and administrative experience in the details of public health as in one of the departments of the Cape Town Colonial Office," if correctly quoted or paraphrased by you, is a deliberate misstatement on the part of your informant. Excepting during the short time he was occupied on the census (and you will appreciate how essential it is that a medical man should be associated with such work and the fund of local information a medical man so occupied must have acquired), Dr. Gregory has been entirely employed in public health work, first as acting medical officer of health, then from August, 1895, to August, 1900, as assistant medical officer of health, and since August, 1900, as medical officer of health for the Colony.

Whether when Dr. Gregory came to the Cape he had ever held a public health appointment I am unable to say; I never asked him. I found an exceptionally able colleague and that was all I cared about. But at any rate he must have given a certain amount of attention to the subject of public health matters, because in 1891 he obtained the Diploma of Public Health of the Conjoint Board. Few men have had a training better suited to a health officer. Dr. Gregory began life as a civil engineer, and the knowledge he then acquired is clearly shown whenever he has to deal with by-laws relating to construction and sewers.

When I came out to South Africa I found that Dr. Gregory had already drafted a Public Health Act which was admirably adapted to the colony. I am afraid that draft Act of his deprived him of the appointment in 1895. Every municipality was up in arms. The author of the Act was by no means a *persona grata*. Pressure was brought to bear and he lost the appointment. There is no doubt that had the Act, as Dr. Gregory originally drafted it, been enacted, instead of the farce now on the Statute Book, Cape Town would not have been in the filthy condition it was when the plague made its appearance. In connexion with the plague the Cape Colony owes a debt of gratitude to Dr. Gregory. It was Dr. Gregory who demonstrated that plague had already reached Lorenzo Marques in 1898 and that a case had even penetrated inland as far as Middleburg in the Transvaal. Again, it was Dr. Gregory who detected plague on the steamship *Kilburn*. I was ill in bed at the time, though I got up to superintend the plague camp. It was Dr. Gregory who recognised plague at King Williamstown, and it is due to him it was stamped out. Again, it was Dr. Gregory who showed that rats had been dying from plague at the south arm of the Cape Town docks, although one expert said they were suffering from a new disease and suggested it might be beneficially introduced into India, and it was Dr. Gregory who established the diagnosis of plague in the case first recognised and who traced out some of the preceding cases. Had Dr. Gregory's instructions been implicitly carried out, had the rats which first died been put into the bottles he had provided for such a contingency, and had the animals been sent to the laboratory, there is no doubt whatever that the danger would have been detected months previously, and who can say whether it might not then have been possible to frustrate the epidemic. It is hardly conceivable that such an order could have been so scandalously disregarded and that disobedience entailing so serious a result should have escaped censure, much less punishment. The work connected with the two last-mentioned invasions Dr. Gregory had to superintend

entirely, as I was away from Cape Colony; but though I was not present I have had ample opportunity by means of printed documents and letters from various medical friends to know all that occurred.

It is disgusting to find that, after working night and day, at first in face of much distrust and opposition, and eventually demonstrating in the most brilliant manner his capacity to fill the post to which he has been elected, two medical men could be found to bring forward such a proposal as that put before the Cape Medical Council.

I will not apologise for inflicting a long letter on you, as I am defending a valuable public servant who is being badly used and who is so placed that he cannot defend himself. My friend is by no means perfect. He is too straightforward and impatient of humbug to be diplomatic, and his language, while always correct, is frequently unnecessarily blunt, and that peculiarity occasionally makes him enemies. But I maintain that Dr. Gregory has a high conception of his duty, that he acts up to it and is incapable of a mean or unkind action, and that he is eminently qualified for his position. I greatly regret that circumstances have severed our official connexion.

I am, Sirs, your obedient servant,

GEORGE TURNER,

Medical Officer of Health for the Transvaal.

Office No. 12, Government Buildings, Pretoria, Sept. 18th, 1901.

P.S.—I see that one correspondent signs himself "Fair Play." This reminds me that the late Dr. Alfred Swayne Taylor, speaking about anonymous letters, used to say that they were signed "Ajax," "Audax," and all sorts of words ending in "ax," excepting "mendax"; but I suppose a signature is *une quantité négligeable* for the Greater Britain people.

\* \* We are glad to publish Dr. George Turner's vindication of Dr. Gregory. The inconvenience caused to Dr. Gregory (and we extremely regret it) is a cogent illustration of the need that exists for a British medical man to keep his name upon the Medical Register. The presence of Dr. Gregory's name and qualifications upon the Register would have shown us that he possessed the D.P.H. qualification, and our remarks, of course, would not have been made.—ED. L.

## THE SANITARY STATE OF TORQUAY.

To the Editors of THE LANCET.

SIRS,—It is with much reluctance that I write to call your attention to the serious contamination of the air of a large portion of Torquay, and it is only after finding that repeated representations on this subject to the town council from myself and others have failed to awaken them to anything like a just appreciation of the state of matters that I appeal to you on public grounds to inquire into things of such vital importance to a large number of people, a considerable portion of whom have come into the place for the benefit of its air.

Torquay, as I may remind you, is spread over an extensive area of hilly ground which, roughly speaking, is of square shape, presenting three sides to the sea and one to the high tableland of Dartmoor. The mildness of its climate both in summer and in winter is dependent upon these sources of air-supply, and in particular the coolness of its summer on the higher ground is largely due to what used to be the pleasant breezes which blow down from the moorland. To safeguard such breezes from contamination would strike most people as a matter of primary importance, not only to the health of the inhabitants, but to the very existence of the town as a health resort. But apparently the governing body of the town thinks otherwise, for whilst with commendable zeal it has freely spent the public money to secure an uncontaminated water-supply from the moors it has with singular perversity done its best to contaminate the moorland breezes by placing under the worst possible local conditions a refuse destructor in that part of the town which looks towards the moors.

I will now try to explain the peculiar features of the site. Of the large area over which the town spreads the valleys for the most part are closely packed with houses, whilst on the hills and slopes the houses mostly stand in gardens. In this way a very long sinuous limestone valley forms a kind of backbone to the town, its lower part being now called Fleet-street and Union-street, whilst its upper part is called the

Upton Valley. It is along the Upton Valley that the town has grown outwards towards the moors, and its further part is closely packed with houses occupied by some of the poorer classes of the community. The valley finally ends in a narrow gorge, which is almost closed by two lofty limestone cliffs. Now what was the site chosen for the chimney of the destructor? The top of a hill, every one would naturally answer, so that the fumes might be wafted away in the upper currents of air far above the town. No; it is placed down in the valley. And where in the valley? At the base of the cliffs and in the angle between their faces. And where is the chimney-top? The chimney, tall and ugly as it is, just reaches to the top of these cliffs, so that it actually leaves off just where it ought to begin. What follows from the violation of every principle that should have guided the *homo sapiens* in such a work might have been easily anticipated. When the wind blows strongly, and more especially when it is northerly or westerly, currents of air pour over the cliffs in cataracts, sweeping down the smoke and fumes issuing from the chimney and rolling them about till they impinge upon the higher ground encircling the valley. And whatever the direction of the wind may be some part of the surrounding district must suffer. Thus my own house, being situated to the south of the chimney and on a level with its top, with a northerly wind the smoke-fumes are blown straight to my quarter, filling my garden and my rooms with a nauseous and acrid belch. Again, with an easterly wind the Teignmouth-road suffers in like manner, and with a westerly wind various parts of St. Marychurch and the St. Marychurch-road, and so on. The nuisance causes serious injury to health, such as headache, nausea, sore gums, with a peculiarly nasty and persistent taste in the mouth, sore-throat, and sometimes vomiting and diarrhoea, and to people with delicate throats and chests it is a serious menace to life. Some invalid ladies living near me are cruelly persecuted by the nuisance, frequently having to rise in the night to shut down, not only the windows, but the chimney registers. I could name many similar instances. I myself have often been awakened in the night by a sudden invasion of my bedroom by the belch. Not only is all enjoyment of life thus effectually destroyed for the time, but a condition of nervous depression is induced by the foreboding that at any hour of the day or night one's house may be rendered almost untenable. Before the nuisance came I myself never experienced even a day's indisposition here, and in particular I used to enjoy in the summer the cool moorland breezes; but now I frequently suffer from headache and sore-throat, and I await these breezes with dread. There is a penalty for adulterating certain kinds of foods; is there none for contaminating that most necessary of all foods—air?

We have now passed through the third summer of the nuisance and its removal is not yet in sight. Forewarnings of the consequences of placing the chimney where it is were unheeded by the authorities. On Jan. 20th, 1897, the morning of the inquiry by the inspector of the Local Government Board (Colonel Durnford), a deputation consisting of some of the influential inhabitants of the district attended to protest against the proposed site, and a petition signed by owners and ratepayers, together with an important letter from Colonel Acton, was presented in support of their protest. Their objections were met by a well-organised band of town officials, the borough engineer producing a drawing which represented the chimney projecting apparently far above the cliffs. The chimney actually erected, as I have mentioned already, does not rise above the cliffs. It is, in fact, 50 feet shorter than the one sanctioned by the Local Government Board. Complaints respecting the nuisance have been met by the town authorities all along in a captious spirit, and every effort has been made to throw discredit upon them. It was not, indeed, until the spring of last year that they were admitted to have any foundation whatever. In the course of the ensuing summer the nuisance became so intolerable that a petition was numerously signed in the districts asking for its removal. St. Marychurch then had its own district council, which warmly took up the complaints of its own ratepayers, and so it sent a deputation to the Torquay Town Council for their presentation. I myself attended at the same time as one of the deputation of the Torquay petitioners. The mayor (Mr. Beavis), who was present when the deputation was received, promised complete redress. He said that everything should be tried to remove the nuisance and that if other measures failed the chimney should be removed. A new fume-cremator was promised to

begin with, and this, after the lapse of several weeks, was put in. After giving a long and patient trial to this remedy, the effect of which was to tone down the stink only to a slight extent, the nuisance at length became so intolerable that another numerously signed petition from Torquay and St. Marychurch, which had now become part of the borough, was sent in to the town council pointing out that whilst the appliances of the destructor might be still incomplete the main cause of the nuisance was the admittedly wrong position of the chimney. The petition earnestly requested the council to take into serious consideration measures for removing the chimney to a suitable site. On May 3rd the petition was placed in the hands of the present mayor who duly presented it to the council, by whom it was referred to the Destructor Committee. The latter, after a good deal of embarrassment, at length fetched down the patentee of the destructor in the hope that he might help them out of their fix. The only good resulting from the conference was some improvement in the stoking, for which there was abundant room, but the root of the evil remained untouched. Meanwhile the nuisance has continued and at times has been well-nigh intolerable. For instance, last Monday and Tuesday, in the squally weather which then prevailed, the condition of the atmosphere was simply disgraceful and a great many people were made ill.

The town council evidently will do nothing until strong pressure is brought to bear upon it from the outside public. Many of them apparently think that stink is a normal accompaniment of the atmosphere—at least, this is the only conclusion I can form from things which they have said. A written communication, too, which I have carefully preserved, from a high official of the town conveys the same impression. I apparently have spoken to deaf ears, but I venture to think that a few plain words from you, Sirs, may have some effect. I am, Sirs, yours faithfully,

HENRY HUMPHREYS, M.A., M.D. Camb., M.R.C.P. Lond.  
St. Marychurch-road, Torquay, Oct. 12th, 1901.

## THE ISSUE REGARDING THE ETIOLOGY OF PERNICIOUS ANÆMIA DEFINED "A DEFINITE INFECTIVE DISEASE."

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to point out, to prevent any possible misunderstanding, that the interpretation put upon my recent work on the above subject by a reviewer in THE LANCET of Sept. 28th, p. 851, is in very truth, as he himself courteously admits it may be, quite "a false one"; and that all the difficulties he with great care points out arise out of his interpretation and have really no existence. The mistake has arisen from divorcing a single sentence from its context, both immediate and remote, notwithstanding that in my Preface I especially request that this must not be done.

If typhoid fever were thought to be a form of diarrhoea—a "pernicious diarrhoea"—producible by many causes, such as indigestion, bad food, weakness of constitution, wasting diseases, &c., and anyone asserted without further premiss that "the chief source or cause of the disease was drinking sewage-polluted water or sometimes, possibly, mere exposure to drain smells" (without the intervention of bad water), this would be nonsense, since it could be at once pointed out that many people drink sewage-polluted water or are constantly exposed to drain smells without contracting this particular form of diarrhoea. But as soon as it is made clear that this so-called "pernicious diarrhoea" cannot be produced by such general causes, but is in reality a special infective disease caused by a special infection, the first statement becomes quite clear. It is understood at once that sewage pollution or bad smells *per se* are not the primary cause, but merely the more immediate sources or causes which determine the onset of the disease in the particular case. And if one had not discovered or isolated the particular organism that constituted the special infection—as for many years was the case after it was shown by Sir William Jenner to be a special infective disease distinct from typhus fever—the most important point in its etiology would undoubtedly be the fact of its sewage origin. Without the slightest ambiguity of meaning, therefore, one can say that "*typhoid fever is a special infective disease of filth nature and of sewage origin.*"

Now, Sirs, it is a definite conclusion of this kind that I

have arrived at regarding "pernicious anæmia." It is not merely a form of anæmia, but a *special infective disease*. The sentence which has misled so grievously (and has been so surprisingly interpreted since it is made clear by the very statements quoted that that interpretation is quite wrong) is of the same character and in practically the same terms as the above statement with regard to typhoid fever. If applied to pernicious anæmia as a disease, which I considered could be produced by all sorts of general causes and morbid conditions (as is the generally accepted teaching), it would be absurd to say of it that its chief source or cause was some local sepsis in the mouth; for notoriously such sepsis is as common as pernicious anæmia is rare. *But it is not to any such general disease or morbid state that the statement is applied.* On the contrary, it is applied to a disease which, as the outcome of work detailed in the preceding 250 cases, I find to be "not merely a special anæmia but in reality a special and well-characterised infective disease—one that cannot be produced by any of the ordinary factors of anæmia, *however severe they may be*" (Preface), included among such factors by special mention being "dental caries, stomatitis, glossitis, and all other gastro-intestinal conditions" (p. 204); a disease of which I have to state with utmost emphasis as the outcome of facts detailed that "in my own mind no fact stands out more clearly in connexion with the etiology of the disease than that none of the above conditions—so-called 'causes'—can of themselves produce the disease of pernicious anæmia with all its characteristic hæmolytic changes" (p. 225).

When immediately following such statements (surely clear and emphatic enough) I go on (p. 227) to define the disease as "a special infective disease caused by a special infection," and proceed in the very next sentence to speak about this infection and the part that oral sepsis plays in connexion with it, it is quite clear that such words as "causes," "source of infection" are now being used in the strictly subordinate sense in which they are daily used in connexion with the onset of an infective disease—viz., not as the causes which determine the existence of the infection in the first instance, but those which determine its taking root in the body. [The question of the primary nature and source of infection, as a matter of fact, I leave quite open (p. 225).] It is a rôle of this kind—*of the utmost importance, but always subordinate to the special infection underlying the disease*—that oral sepsis and its local effects play in the etiology of pernicious anæmia. "The disease is a definite and well-characterised special infective disease—one in which oral and gastric sepsis plays an important antecedent and concurrent part" (Preface). What this part is I describe at great length—viz., creating the subacute and chronic catarrhal glossitis and gastritis, or in some cases enteritis, which enable the infection to take root (its "antecedent rôle"); in all probability also operating in another way—viz., by determining the degree of virulence of the special infection—an action exceedingly probable—or by acting along with it as a "mixed infection" ("concurrent" rôle).

Such is the clear and definite issue I have raised regarding the etiology of this disease. There is no dubiety about its character. It is brought out in every section of my recent work from the opening inquiry which heads the first chapter, "What is Pernicious Anæmia?" up to the final conclusions which I have just given. And to avoid all possible oversight I bring out these conclusions once more in the Preface. The issue is this: (1) "none of the ordinary factors which produce anæmia, however severe they may be, can produce this disease; (2) the disease is really a specially infective disease, characterised by intense hæmolysis (with anæmia) and other, hardly less definite and constant, toxic clinical features; (3) in the development of the disease—i.e., in enabling it to get rooted in the mucosa of the tongue, stomach, or intestine where it has its site—probably also in intensifying its virulence, long standing oral sepsis and its subsequent effects in the stomach and intestine are the most important etiological factors." And so of this "anæmia" (as of the "diarrhoea" of typhoid fever) I can say without the slightest ambiguity of meaning—as I do say—that "it cannot be produced by the ordinary factors causing anæmia (diarrhoea), however severe they may be; on the contrary, it really is a special infective disease.....of septic nature (of filth nature).....and of septic origin (of sewage nature)."

This being the issue clearly and emphatically set forth, it can be no less clearly met and dealt with—viz., by showing on extended grounds covering the morbid anatomy, infective nature, clinical features, and etiology of the disease:

1. That the disease with its distinctive hæmolytic changes *can be* produced by all ordinary causes of anæmia.
2. That it is *not* an infective disease limited to the mucosa of tongue, stomach, or intestine; in particular, that recurrent glossitis of a special, recurring, and peculiarly persistent character—the most obvious manifestation of its lesions—does not occur.
3. That sepsis—oral, gastric, or intestinal, singly or combined—plays no part in the development of the disease, as evidenced by the absence of their clinical or pathological manifestations—namely: (a) no history of oral sepsis or of stomatitis or soreness of mouth previously to or at the time of onset of the disease; (b) no history of periodic gastric trouble (nausea, sickness, or vomiting); (c) no history of periodical intestinal troubles (looseness or diarrhoea).

But if this issue is to be dealt with *it must not be obscured by ignoring the first two vital portions of it*, and by representing that the third alone is the chief, still less that it is the whole, issue raised by my work. Nor need it be so put that I have been led by interest in the subject of oral sepsis and its gastric effects to attach an undue importance to their presence and possible rôle in pernicious anæmia. For, as a matter of fact, as I have pointed out elsewhere, it has been the study of their rôle in pernicious anæmia that first directed my attention to, and led me to investigate, their possible importance in other and much simpler conditions. The matter is not one that is capable of being decided by any controversy, but only by observations on the disease itself in the light of the new class of facts now raised for consideration; and it is solely with a view to promote such further observations that I have now been induced to write.

I am, Sirs, yours faithfully,

Harley-street, W., Oct. 7th, 1901.

WILLIAM HUNTER.

## THE REORGANISATION OF THE ARMY MEDICAL SERVICES.

*To the Editors of THE LANCET.*

SIRS,—With your permission I propose to make a few remarks on this important national topic, apologising for the necessarily lengthened character of this communication. The report does not profess to take in hand all the recommendations made by the South African Commission, but, leaving the organisation of the Royal Army Medical Corps intact, it furnishes a scheme providing a body for carrying out these recommendations, while mainly contenting itself with the development of the medical *personnel* to the requirements of scientific progress and medico-military advance and rectifying recognised defects. How far the proposals are of a satisfactory character and how far the scheme is open to fair criticism are points on which probably much difference of opinion will exist. Personally I approach the subject from a present outside standpoint with an experience of some 35 years of the inner working of this departmental system, within the period embraced. Though the report is so far but a series of proposals it doubtless will constitute the foundation on which a Royal Warrant will be built and hence indicates the intentions of the War Office in the future of the corps in respect to the points touched upon. I arrange my remarks as follows.

1. *The constitution of the Advisory Board.*—It is to consist of four army medical officers, four civil medical men, and a representative of the War Office and of the India Office respectively. In it we recognise the old Consultative Board of the Crimean Committee reproduced, qualified by the addition of the civil medical element and of the officials referred to. Equally balanced as the components are it contains no deciding voice. The professional element predominates, but in the event of disagreement between the military and civil sections the deciding factor rests with the officials. It may be fairly questioned whether the proposed new board is an advance over the old board comprised of four selected army medical men of the highest grade with full experience of army needs, especially as at present constituted. The military section can be overruled by the six members with no close personal experience of army work and its requirements. And this point is of more importance as by Paragraph 7 this board has to submit a scheme dealing with war requisites—ambulances, transport, equipment of medical units, provision of *personnel*, &c.—and by Paragraph 14 the retention and promotion of officers in the service will be referred to it, including the appointment of a Director-General. It is true that by Paragraph 12—inspection of hospitals by a sub-committee—

some of its members may obtain a little personal experience of some of the army medical men, yet outside this it is difficult to perceive how the requisite knowledge for guidance in such matters is to be obtained sufficient to place them in a position equivalent to the four army medical men whose personal experience must be far in advance of them and whom conjointly with the War Office and the Indian officials they may override. And in respect to the inspection of military hospitals by a sub-committee, is such inspection to supersede that made by the principal medical officer of an army corps or district? and is it to be limited to the United Kingdom, excluding the numerous hospitals scattered abroad and possibly far more requiring the specified supervision?

2. *The Director-General.*—In the scheme the old process is continued which practically leaves the appointment in the hands of the Commander-in-Chief and so gives him a dominant control over the higher officers at least. It is true that the Commander-in-Chief is by Paragraph 17 to act "with the advice of the Advisory Board," yet it may be confidently anticipated that the selected man will require to be at least a *persona grata* to the Commander-in-Chief. The defect appears to be that there is no guarantee that the ablest and best man for the post will fill it, while there is full scope for the predilections and personal views of this military official which we know from the past may be anything but conducive to a well-organised and efficient medical corps. No less defective is the questionable responsibility of the Director-General. While apparently having no seat at the Army Board and subordinate to the combatant section of the War Office he is, by Paragraphs 18 and 19, held responsible for the administration of the army medical services, for promotion and for their general organisation, yet neither in respect to the provision of requisites for army needs nor to organisation nor to promotion has he a deciding voice, but the first of these rests by Paragraphs 6 and 7 with the Advisory Board (of which he is one among eight units) and the Secretary of State and the last is divided among the board generally subject to the control of the Commander-in-Chief. The arrangement as proposed permits of the assessment of future responsibility in these matters against the Director-General or the impersonal board, or the Secretary of State or the Commander-in-Chief as one or other paragraph may be regarded as binding; in other words, it provides a scapegoat or permits such a division of responsibility as to defy any personal application of it. If anything the responsibility of the future Director-General is lessened by the Advisory Board, while his subjection to the combatant branch as personified by the Commander-in-Chief remains in full force.

3. *The supply of medical officers.*—The increased rates of pay per annum, the charge and specialist pay, are decidedly conducive to numerical increase of applicants as compared with recent years, while on the other hand the requisite conditions are far more stringent, and the question is, which will be the determinate factor in the future supply? The candidate must produce such evidence as is required of character, conduct, professional ability, and fitness for a commission, he must be physically fit and pass a clinical and practical examination in medicine and surgery, following which he has to undergo instruction and examination at Netley and a similar process at Aldershot in prescribed subjects, the qualifying test being a percentage of 50 of the marks set and failure after a second attempt leading to rejection; if successful his position on the list is determined by the combined results of these three examinations. Considering that the candidate is already a qualified medical man, entitled to practise, the test for a commission is a stringent one and one, probably, which none but those above the average would care to face, especially when taken in conjunction with the subsequent tests.

4. *Conditions governing the future army career.*—After having served as a lieutenant for three years in a corps or army unit the officer may retire, or if well reported on may join the reserve for seven years at £25 per annum or continue on in the service. Should he select the latter he commences a series of examinations, three in number, guarding the approach to each step in rank, the qualifying test being either 40 or 50 per cent. of the value of the questions set, each examination being preceded by a separate course of study, taken at a specified time as a rule, the subjects becoming less professional and more of a medico-military and administrative character as the examinations progress, the results if of a high order leading

to a graduated acceleration of promotion, if below the qualifying test permitting of a second chance, failure in which entails retirement from the service. No pecuniary gratuity on retirement is allowed until after nine years of service when it amounts to £1000, and after 18 years when it is increased to £2500; hence, failure to meet the earlier examination requirements will necessitate the professional man commencing civil life unaided by any pecuniary reward for any service under nine years. Up to the rank of major seniority tempered by possible accelerated service governs the progress of the individual; for a lieutenant-colonelcy selection comes into force from a list of those qualified for administrative work as tested by the last required examination—the sixth from the application for admission into the corps—50 per cent. of the marks set being required; and for the higher grades selection prevails. The questions arise: Will not these numerous examinations, necessitating a high standard, operate as a deterrent to the young qualified man already wearied by the numerous tests required under the Conjoint scheme? And, moreover, provided the right men be obtained in the first instance, are they necessary reasonably to safeguard the service? Would not one examination after the entrance test, with gradations as proposed in accordance with standard passed, and selection to lieutenant-colonelcy onwards, suffice? That the principle is good may be granted, but the execution of it leaves much to be desired. The formation of a "bookworm" seems the likely result and not the good all-round officer which the service needs. Continuous study will be essential, and the thought occurs, Where is the time for obtaining all this theoretical knowledge and for the practical army work to be found? Where do reasonable recreation, social duties, and other scientific pursuits come in? And from the administrative point of view a difficulty in meeting the possible requirements will soon make itself felt. To permit of the application of the scheme a very decided increase of *personnel* is essential, not only for this provision but also for the lieutenants attached to corps or units, and will this increase be forthcoming? How will the foreign service be arranged, the lieutenant stage being apparently passed at home, so as to permit of the study leave, attendance at practice of civil hospitals and the acquirement of knowledge of the professional advances made? How can these be carried out under war or other pressure? How can the chances of each individual, scattered as the service is over such a wide area and with such variable opportunities of obtaining the required knowledge, be made equal—in other words, fair play given—in view of this graded acceleration of promotion operating at each step in rank? Whether the entry of men will equal the demands remains to be seen; but, the required numbers obtained, the difficulties of placing the scheme on a sound fair working basis cannot but be great, and probably will indicate it as unworkable should unfavourable conditions prevail. The system proposed seems overburdened by unnecessary restrictions.

5. *Promotion by selection to the administrative grades.*—This neglected and cast-off principle of the Herbert warrant is again revived, yet the grounds on which it is to be based are curiously omitted in the scheme. It is to operate for the rank of lieutenant-colonel and upwards, through the Advisory Board (including the Director-General) and rest in the Commander-in-Chief. What may be the respective powers of those having a voice in determining the result, what may be the strict responsibility of the Director-General in the matter, what may be the influence of the Commander-in-Chief, so far as opposing or supporting the principle or controlling its individual application; whether in this professional corps professional and scientific attainments shall receive full consideration or the old baneful course be followed, or what qualities shall be taken into consideration—these are all doubtful details. That this is not a mere academic question, but one of great practical value, will be apparent in view of the power resting in the Commander-in-Chief touching promotion, of the impotence of former professional departmental heads to safeguard the special provision of the Royal Warrant following the Crimean Commission touching selection for merit, and of the course taken in the past in advancing individuals over the heads of others. The grounds on which selection is to be based require to be stated and some guarantee given that the conditions shall be fairly and honestly observed, and this is a point well worth the careful consideration of any highly qualified and talented professional man before embarking on an army career. The past will not bear inquiry.

6. *Concluding remarks.*—That the scheme, as a whole, is based on right principles and is an honest attempt to remedy the defects will probably be granted, though whether the details are likely to effect the desired objects may be fairly doubted. The provision of brevet rank, charge pay for certain large hospitals (a tardy acknowledgment of the justice of the appeal made by some executive officers in India in the past without result), devolution of powers from the head office to the principal medical officers of corps and districts, provision of means of instruction in field medical duties at the headquarters of each army corps, and the relief of clerical work, all are of unquestionable value, though the separation of the medical officers of the Household Brigade from the corps can hardly be placed in the same category. Apparently the Netley School is doomed, though a substitute is provided in the proposed military hospital and Medical Staff College (Millbank?). The scheme falls short of that of Lord Herbert in the lack of provision for sanitary means and supervision—a detail fully justifying the exception taken by Professor A. Ogston—and this is a strange omission in view of the fact that the primary *raison d'être* of the corps is not curative but preventive medicine, and of the repetition in this war of former experiences of the enormous preponderance of disease over war injuries in the curtailment of efficiency of armies in the field. How far the scheme will bring about a corps capable of efficiently performing the duties entrusted to it to the benefit of the army and State will depend on the spirit in which it is met by the service at large—especially the combatant branch—and the official heads, and on the degree to which free play is given for action by the army and medical regulations. As was well put by Major-General Sir Ian Hamilton: "Recollecting that it was but a framework its scientific possibilities in sympathetic hands would be understood. There would come the rub—the hands must be sympathetic and kindly, and not only the hands of the War Office but those of the Government of India." Just so; the power residing in the Secretary of State for War and in the Commander-in-Chief—including under him the army sections under his influence and sway—to make or mar the scheme is beyond doubt, a fact fully attested by the action taken in the past ending in the destruction of the Magna Charta of the Medical Department, a Royal Warrant notwithstanding. And no one who has "gone through the mill" will doubt the power of army regulations and orders to bring to nought the best devised schemes which clash with the views of the military caste. The unfortunate feature in all such schemes, including warrants, is that there is no guarantee for their observance. So far as this one is concerned the aspirant for army medical service may fairly rely on his pay and on the recognition of his professional attainments to the rank of major, but in respect to provision of the means enabling him to meet the requirements of the numerous examinations, in respect to promotion to the higher grades through professional merit and scientific attainments, in respect to having full scope for the abilities he possesses and the desire to work, in respect to obtaining opportunities for scientific pursuits, he is in the hands of others, and past experience, unfortunately, is a warning against undue sanguineness on such and other points.

I am, Sirs, yours faithfully,

FRANCIS H. WELCH, F.R.C.S. Eng.,  
Surgeon-Colonel (retired), A.M.S.

Lee, Oct. 14th, 1901.

## MILD CASES OF SMALL-POX.

To the Editors of THE LANCET.

SIRS,—I am very glad to see by your leading article of Sept. 21st that Mr. Wynter Blyth has suggested that the Metropolitan Asylums Board should publish illustrations of actual cases of mild small-pox for the benefit of those practitioners who are unacquainted with the disease at sight. Would it not be a boon to students, teachers, and practitioners generally if the medical officers of the Board could be prevailed upon to issue a small series of similar illustrations? My experience of the early erythematous and hæmorrhagic eruptions of small-pox is that they are seldom recognised at their onset by physicians who have not had special experience of a small-pox epidemic. In common with many others I learnt to diagnose chicken-pox by studying the cases erroneously sent into a small-pox hospital during a small-pox epidemic. The hæmorrhagic varieties

of the ordinary infectious diseases are always worth portraying, to say nothing of the typical rashes of typhus fever, enteric fever, scarlet fever, measles, and rubella. Perhaps there might be added some of the rarer forms of diphtheria, with membrane on the conjunctiva or on open wounds, or even an illustration of the rashes which sometimes follow injections of antitoxic serum. I venture to extend the scope of the original suggestion because I do not know of any similar atlas already existing for infectious diseases. If, however, there is one, perhaps you or one of your readers will be so kind as to inform me.

I am, Sirs, yours faithfully,

Cairo, Oct. 1st, 1901.

F. M. SANDWITH, M.D. Durh.

## "THE AFTER-COMING HEAD; PREVENTION OF ASPHYXIA."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Sept. 21st, p. 815, Dr. Edwin Smith suggests the introduction of a catheter into the child's mouth in cases of breech presentation in which the head is delayed in delivery. In Barnes's "Obstetric Operations," second edition, 1871, page 198, it is stated: "You may sometimes get the tip of a finger in the child's mouth, and drawing this down, whilst you lift up and draw back the perineum, you may enable air to enter the chest. In this way I have kept a child breathing for 10 minutes before the head was born. Another plan is to pass a catheter or other tube into the mouth so as to give by means of a kind of artificial trachea communication with the external air, or better still Richardson's bellows." It will be seen, therefore, that this line of treatment was advocated 30 years ago. "There is nothing new under the sun," not even in midwifery.

I am, Sirs, yours faithfully,

C. H. L. JOHNSTON, M.D., L.R.C.S., and L.M. Edin.  
St. John, New Brunswick, Oct. 3rd, 1901.

## THE FORTHCOMING ISSUE OF THE MEDICAL DIRECTORY.

To the Editors of THE LANCET.

SIRS,—If you can spare a little space in the next issue of THE LANCET we shall feel much obliged by your warning your readers of the approaching publication of the Medical Directory for 1902. It is well known that the volume cannot be accurate unless all the latest information is supplied to us by the profession and various secretaries of medical institutions, and as we are now about to make up for the press any additions or alterations should be posted to us at once.

We are, Sirs, your obedient servants,

J. & A. CHURCHILL.

7, Great Marlborough-street, London, W., Oct. 12th, 1901.

## "A MEDICO-LEGAL SOCIETY."

To the Editors of THE LANCET.

SIRS,—I do not, of course, know who "M.D., D.P.H." may be, but I am quite with him and willing to become an original member of a medico-legal society, and to help to promote such a society.

I am, Sirs, yours faithfully,

FRED. J. SMITH,

Lecturer on Medical Jurisprudence, London Hospital.

Oct. 13th, 1901.

## "WORKHOUSE NURSING."

To the Editors of THE LANCET.

SIRS,—By some process of mental gymnastics Mr. F. R. Humphreys has persuaded himself that in my last letter I represented Miss Twining as stating that her plan had been annexed by Mr. Humphreys.

The opinion there expressed is my own and not that of Miss Twining and it has been deliberately formed after reading her writings, kindly sent by her and published before Mr. Humphreys thought fit to announce the plan as his own, and my object in drawing attention to this will have been attained now that Miss Twining's rights as the author of the scheme have been established. Is not Mr. Humphreys fluttering on rather a lofty perch when he charges me with "flagrant conduct" because I do not humbly withdraw my formed opinions at his august bidding? It is an unfortunate

characteristic of our public life that any ambitious amateur, if endowed with sufficient pertinacity, can always obtain a hearing and if backed with sufficient noise can sometimes overcome expert professional opinion. I hope Mr. Humphreys will give me an opportunity of joining issue with him in the pages of the "great monthly magazine."

I am, Sirs, yours faithfully,

F. S. TOOGOOD, M.D. Lond.

Lewisham Infirmary, High-street, Lewisham, Oct. 14th, 1901.

## CLUB PRACTICE.

*To the Editors of THE LANCET.*

SIRS,—I am instructed by the Stockton, Thornaby, and District Medical Association to lay before you the following facts. Some months ago this association unanimously passed a resolution that no member would accept or hold any appointment to a friendly, trade, or yearly society at less than an annual fee of 4s. for adults and 3s. for juveniles. The societies in question agreed to this, but now an amalgamation has taken place between certain of them and they are attempting to obtain the services of an outside medical man at a lower rate of remuneration. The members of the Association have pledged themselves to hold no professional relations with any medical man who may accept the post. By making these facts known in THE LANCET you will oblige, and at the same time may prevent any medical man applying for a post the remuneration for which is inadequate and its disadvantages necessarily very great. Thanking you in anticipation,

I am, Sirs, yours faithfully,

FRED. G. SMITH,  
Joint Secretary.

Oct. 13th, 1901.

## "TUBERCULOSIS AND HEREDITY."

*To the Editors of THE LANCET.*

SIRS,—I should like emphatically to endorse Sir W. Gowers's remarks in THE LANCET of Oct. 12th (p. 1007) as to the importance of heredity and predisposition in the etiology of tuberculous disease. At the present time the tendency is to exalt unduly the importance of extrinsic factors in the causation of disease and to ignore the intrinsic factors. Yet for preventive and therapeutic purposes the latter are often the more important, and that this is the case with tuberculosis I propose to show. The discovery of the tubercle bacillus was a great triumph for the bacteriologist, but it has not done much for the more effectual prevention and treatment of the disease. Long before its discovery remarkable diminution had been effected in the mortality from tuberculous disease in this country by the introduction of methods that tended to strengthen the predisposition of the organism against the disease, and to the continued operation of such factors the present diminishing mortality from the disease is undoubtedly due. Instead of being encouraged to persevere along these and kindred lines the profession has been misled by bacteriologists to entertain the delusion, that the disease may be prevented by exterminating the special microbes or by preventing their access to the body—both of which expectations are futile. Because a few living tubercle microbes were found in a roll of beef that had been cooked in the ordinary way a learned commission somewhat hastily concluded that the disease was therefore spread by eating such meat, &c. If this were so the tubercle mortality would have doubled during the last half-century, for the meat consumption per head has increased in that proportion; but the fact is that the tubercle mortality has diminished by more than one-half. Plenty of good meat—which generally contains some tubercle bacilli—is one of the chief safeguards of crowded urban populations against tuberculosis. Bacteriologists seem to forget that under modern conditions of life it is impossible for anyone to escape from the infection of tubercle; and all schemes for the prevention of the disease based on the contrary supposition are mere fads.

The more thoroughly post-mortem examinations are made the higher is the percentage of tuberculous lesions discovered; until when such examinations are made with the utmost scientific precision almost every body examined is found to present undoubted signs of tubercle. Thus, Naegeli reports that of 500 post-mortem examinations at the Zürich Pathological Institute undoubted signs of tubercle were found in no less than 97 per cent. of all the bodies examined. Now if this be so—and personally I believe it to be true—how can we account for 12 members out of a family of 13

dying from tubercle—as in a case of which I know—otherwise than by predisposition and heredity?

I am, Sirs, yours faithfully,

Clifton, Bristol, Oct. 14th, 1901.

W. ROGER WILLIAMS.

## WORKERS' RESTAURANTS.

*To the Editors of THE LANCET.*

SIRS,—In the course of my daily duties which bring me into close contact with the working girl of the West-end the pressing need of special restaurants for women and girls is constantly presenting itself. It is obvious that for the rapidly growing girl, whose strength is further taxed by sedentary occupations in close rooms for long consecutive hours, abundance of nourishing food is essential. In the workrooms of the dressmakers and milliners of the West-end there are thousands of young girls employed, from the child apprentice earning a weekly half-crown for "pocket-money" to the finished assistant who receives on an average from 15s. to 18s. per week. These are absent from their distant homes for periods of 12 hours and longer, during which time a nourishing meal is unobtainable.

The prices of the West-end restaurants are, needless to remark, beyond the reach of these workers. At the mid-day break the only alternative is a lunch at the tea-shop, where the few pence are spent in worse than useless fare, or the consumption in the workroom of the unappetising dry sandwich. Is it to be wondered at that so many girls break down at the onset—that many more struggle wearily on, battling with that arch enemy to young womanhood, anæmia, which is the forerunner of even worse ills? The point I wish to emphasise is that at present these girls are unable to procure the food of which they are so much in need. I am convinced that it would not be difficult to remedy this state of things by starting special restaurants where good hot meals at cheap rates could be obtained; indeed, I am of opinion that it would be possible to raise capital for such a purpose, and if a sufficient number of these restaurants were started and well managed financial success might be counted upon and a small dividend paid to investors.

Employers would doubtless liberally encourage such an undertaking, and in so doing would be acting in their own interests, while I am sure that many of the ladies who wear the beautiful gowns and millinery which these clever workers produce would gladly become shareholders and so help to confer a boon on those who are labouring for them. I should be glad if employers of labour or others who may be interested in this question would communicate with me, with a view to putting the idea into practical form.

I am, Sirs, yours faithfully,

L. MARGUERITE O'KELL,  
Sanitary Inspector.

Town Hall, St. Marylebone, W., Oct. 9th, 1901.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Recrudescence of Plague in India.—Leprosy in Burdwan.—Original Observations on the Habits of Certain Mosquitoes.*

THE deaths from plague throughout India have been mounting up week by week, and the last return, for the week ending Sept. 14th, shows that 6386 deaths occurred as compared with 4822 in the previous week. The Bombay Presidency is severely affected, 5668 deaths being reported last week, against 4132 in the preceding week, and against only 593 for the corresponding week last year. Of this number 293 deaths occurred in Bombay city, 1235 in Belgaum, 1455 in Kolhapore, 1509 in Dharwar, 107 in Thana, 86 in Surat, 78 in Cutch, and 586 in Satara. In other parts of India the disease is not active, but Calcutta returned 18 deaths, Patna 20 deaths (this is a sudden increase), and Shahabad 32 deaths (a fresh outbreak). In Karachi there were 15 deaths, in Mysore 295, and in the Punjab 16. The chief changes during the week are the recrudescence in Bengal, the continued increase in Bombay city, and the decline in Mysore. The development in Bengal is especially serious because a few weeks ago it was almost clear and because during the last cold weather there was a high mortality in certain districts. Madras city has up to the present been free from plague,

but during the week ending Sept. 7th the death-rate was 105.9 per 1000. Cholera was responsible for 130 deaths, but the large excess in mortality during several weeks past is not satisfactorily explained. Bombay city has now a death-rate of 66.44 per 1000, the excess being partly accounted for by plague. The city of Calcutta, on the other hand, continues to show an exceptionally low death-rate. There is very little plague, cholera, or small-pox.

In a paper on leprosy recently read before the Calcutta Missionary Conference figures were given relating to the Leper Asylum at Raneegunje which show that the disease is four times as prevalent in the Burdwan district as in the rest of India and that of those in the asylum 33 per cent. had either leper parents or a taint in the family. Of the children born after leprosy had been contracted 9 per cent. became lepers. These are higher figures, I believe, than those of the Leprosy Commission.

A paper recently read before the Asiatic Society of Bengal upon the Habits of the Common Grey Mosquito gave detailed evidence that the female may live in its adult stage for nearly five weeks, that during this adult life it may feed as many as five times, and that it does not feed indiscriminately but has a preference for the blood of the house sparrow. The time of laying eggs would seem to depend on the amount of blood taken. If the insect gorged itself the eggs might be laid in four or five days, whereas on a small meal the egg-laying might be delayed to 14 days. After laying her eggs the female may feed again and lay a second batch of eggs, and if she be able to obtain a meal of blood she will continue to do this during her adult life. A fresh observation recorded in the paper concerns the structure which forms a part of the lid of the egg. This is best seen in the eggs taken from the body of the insect when near full term. The eggs are capped at the larger end by a transparent, dome-shaped structure which is delicate and is easily broken off. It probably acts as a float. Inside and at the base of this structure is a cup-shaped cell with a hole or depression in the centre. When the float-cap breaks this cell comes away and becomes flattened out and looks like a star.

Sept. 21st.

*The Week's Plague Figures. — Bombay Mortality. — The Famine Returns. — Disinfection of Wells on the Outbreak of Cholera. — The Death-rate in Madras City.*

This week shows a decline in the number of deaths from plague throughout India. The figures are 5712, as against 6386 for the previous seven days. The most infected places are Bombay city, 236 deaths; Karachi, 11 deaths; Calcutta, 13 deaths; the Bombay Presidency, 4844 deaths; the Bengal districts, 72 deaths; the North-west Provinces, 18 deaths; the Punjab, 57 deaths; and the Mysore State, 342 deaths. In the Bombay districts the chief infected areas are the Poona district, the Satara district, the Surat district, and the Dharwar and Belgaum districts. For the week there is a decline in Bombay city, in Karachi, and in Calcutta, but a rise in the Bengal districts, the Punjab, the North-west Provinces, and the Mysore State. The outlook is ominous.

The letter in the *Times* upon the plague in India deserves further attention. The returns of plague from Bombay city are most misleading. The mortality in this city during the past three years has been enormous and the plague figures only account for part of the excess mortality. It is unlikely that other diseases should have so enormously developed during the plague period as to account for this excess, and the probable explanation lies in the deficient registration of plague deaths. It is high time that further inquiry was made into this anomaly. At the present time the death-rate in this city is nearly 60 per 1000 per annum.

The famine returns still show over 400,000 people as receiving relief. Crop prospects are good in some places, but there has been a deficiency of rain in others, and locusts have caused considerable damage in Bombay, in the Central Provinces, and in Baroda.

It is high time that the farce of colouring the water of the wells and other places with solution of potassium permanganate with the idea of stopping or diminishing outbreaks of cholera should be recognised. A certain amount of organic matter may be destroyed, but that is all. Much more evidence is required to prove its value. In some places after this disinfection cholera has stopped, but in others it has not and the strength of the solution used is not at all likely to kill the cholera bacillus.

The death-rate of Madras still continues excessively high.

It is now about 110 per 1000 or double the mean of the past 10 years. Cholera, dysentery, and diarrhoea seem to be the chief causes of this increase. The districts of the city most affected are those on the north and west. The water-supply is not above suspicion and is liable to contamination. An analysis published in the *Indian Municipal Journal* shows pollution to a considerable degree. It is said that certain villages to the north and west have been affected with cholera for some time past and that from them large numbers of labourers go into Madras daily. The sanitary state of these villages is described as terrible. They are overcrowded and their well-water supply is foul to a degree. Many are dependent for their water on the stagnant pools in which they wash and water their cattle. A death-rate of 150 per 1000 in the First Division certainly demands investigation.

Sept. 27th.

## MUNICIPAL REPRESENTATIVES ON THE HOUSING OF THE POOR:

A CONFERENCE AT GLASGOW.

(FROM OUR SPECIAL COMMISSIONER.)

(Concluded from p. 945.)

THE afternoon sitting of the first day began by the reading of a paper which proved once again that "distance lends enchantment to the view." Bailie D. M. STEVENSON (Glasgow) opened the proceedings by introducing the question of the caretaking of tenements. He attributed the Scotch custom of living in flats instead of separate houses to the intimate relations that had subsisted between Scotland and France. Bailie Stevenson, however, lamented that "when our French allies brought the tenement system to Scotland they omitted to bring the *concierge* with them." It was fortunate for the worthy Bailie that there were no Parisians present, for he even went so far as to specify more particularly the Paris Cerberus who sits and scowls from the dark recess in the side of the *porte cochère*. Bailie Stevenson thought that the caretaker or *concierge* contributed to maintain the order and cleanliness of the dwelling. In practice, however, I have good reason to know that the *concierge* studies scandal rather than sanitation. How many reputations have been destroyed, duels fought, and families broken up through the prying, gossiping proclivities of the *concierge*. Ready to be bribed by home and foreign criminal and political police and private detectives, the *concierge* tampers with the tenants' correspondence, spies upon their visitors, gives incorrect information, spreads false rumours, and generally causes mischief all round. It is only after a harsh experience that the tenant may perhaps overcome these inconveniences by resigning himself to the necessity of plying his *concierge* with numerous soft words and many hard coins. Of course, some *concierges* are very worthy people, and I knew one Parisian *concierge* who warned his Russian tenants that he kept their correspondence back for the Russian political police to read before putting it up on the letter-rack. These, perhaps it may be said, are considerations that have no direct bearing on sanitation; but, on the other hand, it would interfere with the popularity of improved dwellings if anything like the grievances which have grown up around the institution of *concierges* in France were introduced into Scotland or England. Caretakers there should be, living above, below, or on the side of the block of the flats or tenements, but not at the entrance door watching every movement and every visitor, receiving all the correspondence and answering all the questions. The caretaker may be a useful servant but the *concierge* is a terror and a tyrant. The unpopularity of the *concierge* in France should serve as a warning in regard to the manner in which caretaking is organised in England. The *concierge* is essentially a doorkeeper and a spy. What is wanted is a rent-collector who shall at the same time be a caretaker and an inspector. The object is not to interfere with the liberty of the subject by spying out all the details of his private life, but to see that he keeps his home clean and does not inconvenience his neighbours. Paris, however, is a long way from Glasgow, and if the *concierge* suggests many obstacles and objections there is no doubt that in Glasgow the caretaker has rendered good service. Bailie Stevenson related that 10 years ago the Glasgow Workmen's Dwelling Company tried to supply

cheap, wholesome tenements, but the conduct of some of the tenants was such that they would soon have converted model dwellings into new slums. Consequently resident caretakers were appointed and they policed the dwellings so well that the destructive and disorderly tenants were soon driven away or reformed.

Mr. W. C. M'BAIN (Glasgow) thought that there was more done in the way of sifting than of reforming. The root difficulty rested in the tenacity with which a certain class clung to their dirty and shiftless habits. These people must be raised and this would not be accomplished by driving them from one locality to another. Authority to control them was required. This the landlords did not possess, but the corporation, in their capacity as magistrates, had to deal with applications for the eviction of dirty and destructive tenants. As yet, however, the magistrates had not really taken up this question.

Mr. H. C. RICHARDS, M.P., argued that when dealing with the undesirable class of tenants the question of caretaking was most important. The caretaker must be strong, firm, and yet kind and sympathetic. The success of a large block of tenements depended, in the main, on the skill and efficiency of the caretaker. This was the case in the Peabody and Guinness dwellings where they had a good class of tenants, and the good that caretakers could do would be much greater where the residuum was taken in.

Mr. WILLIAM HOLDER (chairman of the Unhealthy Dwellings Sub-Committee of Hull) read a paper on the Clearing of Insanitary Areas. He condemned the extravagances and delays resulting from the application of Part I. of the Housing of the Working Classes Act. At Hull they had applied Part II., though it was only intended for insanitary houses and not for areas; but it was quicker and cheaper to proceed separately against the owner of each house than to try to apply a large scheme. In this manner they had demolished 385 houses in five different districts. This was quite as important as any scheme, but it was not a scheme within the meaning of the Act. Therefore they were able to dispense with the intervention of the Local Government Board. All that they had to do was to be quite certain that the houses which they wished to destroy were really unhealthy. Then they obtained a magistrate's order on the evidence of their own officers, backed by the photographs they took of the places which were visited. They thus proceeded against several contiguous houses, and they had cleared a whole street without incurring any cost. The process was very simple. A house once condemned as unfit for habitation had to be closed. If the owner did not rebuild or repair it he must pull it down. After a short lapse of time, if this was not done the town council proceeded to demolish the house, paid the cost out of the proceeds of the sale of the materials, and gave what balance there might remain to the owner. Some of the houses which had been thus treated at Hull were inhabited by the most depraved population that could possibly be found in a seaport town. It was a moral cleaning of the neighbourhood; the scattered population had now to conform to the more decent conduct of those among whom they had gone to live. Under Part II. of the Act the question of rehousing was not raised; and at Hull, fortunately, there were fairly cheap cottages not too far from the slum districts that had been destroyed.

Councillor INNES (Derby) also read a paper on the subject, and alluded to the affection which people bore for the slums in which they were born. The aged, more especially, preferred ill-ventilated and crowded dwellings. They dreaded brightness and light, and also feared the monotony and dullness, the absence of shops and crowds in the suburban districts. Therefore he urged that theatres, reading-rooms, baths, and large and commodious public-houses should be provided in the suburbs, so as to entice people away from the overcrowded centres.

Alderman M'GUFFIE (Liverpool) boasted that at Liverpool the best means of dealing with the housing problem had been applied. They had preceded even Glasgow by obtaining a local Act in 1864 and this enabled them to deal with insanitary areas. At the cost of £2,000,000 sterling they had dealt with from 10,000 to 12,000 insanitary houses. The speaker seemed to think that the Poor-law authorities should look after the extreme poor and that the city council should attend to the affairs of the rich and the poor alike. People were driven out of insanitary houses not for their good but for the good of the community.

Alderman M'DOUGALL (Manchester) explained that they

had endeavoured to utilise existing dwellings and to render them wholesome by demolishing such structures as prevented a through draught. Thus 800 houses had been pulled down out of 6000, and now the remaining houses had backyards and more air-space. The only cost was that of prosecuting the owners so as to compel them to effect these improvements. The owners were called upon to pull down one out of every four houses or else all the houses would be closed. By these means the bulk of the population were not disturbed, but were kept near to their work and their homes were rendered much more healthy.

Mr. D. S. WATERLOW remarked that these suggestions scarcely applied to London, for the metropolitan magistrates would not give a closing order unless it was shown where the people could be taken when unhoused. Nor did the London authorities take upon themselves to instruct landlords how to render their property sanitary as seemed to have been done in Manchester.

Councillor HOLDER, replying, remarked with regard to the boasted achievements at Liverpool that in no town were there so many waifs and strays and such squalor and misery. Concerning the position in London he thought that the magistrates had no right to insist on rehousing under Part II. of the Act. At Hull private enterprise provided four-roomed cottages for 3s. 9d. per week on the outskirts of the town. The land cost 10s. the yard and the building cost £180. The walls were nine inches thick. The plans were not up to the Local Government Board standard. The fact that Hull was entirely a freehold town greatly simplified matters.

The members of the Conference then adjourned to visit some of the dwellings erected by the Glasgow Corporation, and these interesting investigations were only concluded at the approach of night.

The morning sitting of the second day was opened by Mr. PETER FYFE (chief sanitary inspector of Glasgow) who gave an admirable statistical account of the farmed-out houses. The house-farmer would rent an entire block holding from 10 to 35 one-roomed and two-roomed tenements, and he paid on an average 6s. 9d. per month per room. These rooms the house-farmer furnished with a few absolutely necessary articles which barely cost more than 30s. per room. The house-farmer then let these rooms for 10d. per day, or 5s. per week. Deducting 10 per cent. for unoccupied rooms, Mr. Fyfe calculated that the house-farmers in North Glasgow made a profit of 53½ per cent.; in the eastern districts 70 per cent.; in the southern 60 per cent.; and in the western 63½ per cent. A recent census showed that the average earnings of the tenants were 22s. per week, but they varied from 8s. per week paid to female hairworkers to 42s. 6d. paid to bricklayers and masons. According to the confession made by the inhabitants themselves 47 per cent. had been reduced to this mode of living by intemperance. In some parts of Glasgow from 10 to 20 per cent. of the tenements were not inhabited and were marked "empty." There was room, therefore, to lodge these people, but when it was suggested to them that they should save a pound or two to buy a little furniture they only replied with a sickly smile. They were paying to the house-farmer double the rent they need pay if they only saved to buy a little furniture; but while the public-houses remained open they would never save. He did not think that philanthropic furnishing associations, or municipal lodgings, or the most active of caretakers could help these people. Perhaps a law to prevent the pawning of the necessaries of life might be useful, but the poverty-stricken dipsomaniac could only be cured when alcohol was placed beyond his reach.

Bailie W. F. ANDERSON explained that in Scotland rebuilding was not insisted upon if there were houses available for the evicted tenants within a mile of their former dwellings. The Corporation of Glasgow had bought up the worst property in the town, but the people would not go to the tenements which the corporation had erected; they, on the contrary, endeavoured to find houses even worse than those from which they had been evicted, but as the corporation were destroying the worst houses some improvement had resulted. The municipality had secured the better class of tenants, leaving private enterprise to provide for the worst class. The latter preferred to pay high rents rather than to submit to any sort of control. Bailie Anderson thought that farmed houses should be licensed and controlled by some authority, otherwise those who were displaced would go into other dwellings and convert them into slums.

Dr. A. K. CHALMERS (medical officer of health of Glasgow) read an important paper showing that even with a dense population and in an unwholesome locality the death-rate could be reduced by better housing. The worst district in Glasgow, Bridgegate and the Wynda, had a death-rate of 44 per 1000 in 1891-92. For the two following years the average death-rate was 36 per 1000, and in 1899-1900 it had fallen to 27 per 1000. By the operation of the Improvements Department the population of that district had been reduced from 5689 in 1891 to 4098 in 1900. During these 10 years a portion of the houses on this area had been reconstructed; and during the last two years 1387 persons had been lodged in 361 newly built tenements. Among these people only 40 had died, which was equal to a death-rate of 14.4 per 1000 per annum. On the other hand, in the same district near Jail-square there still remained some of the old tenements which continued to house the old class of tenants up to the adoption of the Improvement Bill in 1897. In this district during the three years preceding the application of the reforms authorised by the Bill the average annual death-rate was 53 per 1000. Therefore, side by side, on a soil equal throughout in pollution, they had one set of poor people with a low death-rate and another set with a high death-rate. Nor was the reduction of the density of population the only factor. If they took the city of Glasgow as a whole it would be found that the density of population amounted to 2.032 persons per room and the death-rate to 21.07 per 1000. The model dwellings built by the Improvement Trust gave a density of population of 2.271 per room and in Catherine-court of 2.526 per room. Thus there was a greater average density of population in these model dwellings, but the deaths were equal only to a death-rate of 15.7 per 1000. These dwellings covered 56.3 per cent. of the site on which they were built. Thus a considerable number of persons could be crowded together if the tenements they inhabited were well built and well managed. It was moral and material filth rather than density of population that produced a high death-rate.

Mr. JOHN MANN, jun., who spoke on behalf of the Workmen's Dwellings Company of Glasgow, urged that it was the housing of disinherited or rejected undesirable tenants which constituted the crux of the problem. Municipal enterprise should deal with the whole of any class, otherwise injustice and privilege would result. Such action also would tend to the benefit of the entire community. Municipal intervention was especially needed in regard to the dangerous residuum, but no congress had suggested how this was to be done, only some details as to the building of a cheap shelter had been given. At present the residuum was left to the mercy of the most unscrupulous of speculators. Under such circumstances it was surprising that so many decent people could still be found in the slums. His company carefully selected their tenants and those who did not respond to the expectations were sent away to drift back into the slums. For such as these the municipality ought to build experimentally cheap blocks or shelters. When these shelters were ready the law against overcrowding should be rigorously enforced and thus the disorderly residuum would be driven from pillar to post. Private enterprise could not do this. The saving in epidemic disease and in crime would compensate the cost of such measures. There were houses where the beds were never cold, for the day tenants succeeded the night tenants in rapid succession, but this pressure would be reduced by the competition of city shelters. For these latter there should be no standard of character. Willingness to enter should be the only qualification. Having thus provided for the needs of the residuum, the police and sanitary authorities should bring full pressure to bear on landlords. The absentee landlords should be followed up and warned that their houses would be closed and condemned as nuisances. The magistrates would no longer hesitate to sanction ejections when it was shown that the tenants could be lodged more healthily in the city shelters.

The LORD PROVOST insisted that there was a considerable class who were not criminals, who earned good wages, often as much as £5 a week, and who yet lived in the most filthy and crowded manner because they squandered their money on drinking. It could not be the duty of the corporation to provide cheap homes for men who earned £5 a week.

Councillor JOSEPH B. COLTON (Liverpool) spoke sarcastically of the bicycles and pianos which he had seen in the Glasgow municipal tenements, while in Liverpool, he maintained, they had striven to house those whose only furniture

consisted of an orange-box for a bed and a tin can for cooking purposes. In Liverpool their by-laws compelled them to spend 8½d. per foot for their building, while in Glasgow they had erected tenements at 4½d. per foot, but they were very inferior to the Liverpool standard. It was not surprising that people resorted to public houses when their homes were so gloomy.

Councillor COOPER (Aberdeen) did not believe in colonising and keeping together members of the same class. At best it only meant a little more room and air; the same social surroundings would produce the same vices. The slum population must be scattered, made to live with a better class, so as to engender in them a sense of shame. It was a mistake to strive to rebuild other, even if more sanitary, slums.

Baillie BROWN (Edinburgh) said that they had spent £150,000 and built a good class of houses, but the residuum would not come and live in them. They had made mistakes, and the more that they knew about the problem the more difficult it seemed. The moral question was the most difficult. What were they to do with prostitutes and with the tenants who said that the municipal houses were too bright to hold their shabby furniture? They had to take in a better class of people, though their object had been to help the inferior, the lowest, class.

Miss HELEN KERR, of the Edinburgh Social Union, wanted to know what percentage of a labourer's wage should go to the payment of rent, but she obtained no answer to her question.

Mrs. D. L. DOCKRELL explained that in Dublin similar difficulties existed, especially that arising from the conversion of houses built for only one family into tenements where many families lived together.

Alderman CARTER (Sheffield) urged that society would not tolerate much longer the squalid condition in which some people lived. Therefore greater powers should be obtained from Parliament to proceed against those who squandered their money. On the other hand, they must be careful that in supplying ready furnished houses they did not encourage improvident early marriages.

Alderman JOWETT (Bradford) attacked the housing of the middle and upper classes of Scotland who, for instance, allowed their servants to sleep in the kitchens where all the food was cooked. The middle classes should give a better example.

Alderman DOYLE of Dublin said that they had been obliged to pay from £5000 to £11,000 per acre for slum land in Dublin, and now the Government refused to sanction further loans. What were they to do? The land and the houses should be accepted as security for the money borrowed.

The discussion was brought to a conclusion after some further description had been given of what had been achieved in Glasgow.

The afternoon sitting was devoted mainly to the consideration of the motions. Mr. JOSEPH B. MASSEY (sanitary inspector of Burnley) found time, however, to read a paper urging municipalities to start cheap tramways to relieve the congestion in the centre of the towns, but this did not lead to a debate. There was a good deal of conversation rather than speech-making over the motions, and some of the words were altered. The words "deserving poor," for instance, were withdrawn and the word "people" was put in their stead, for it was strongly felt that the undeserving poor constituted one of the most important features of the problem. The first motion asserted that it was the duty of the municipal authorities to provide cheaply-constructed but improved dwellings, and that for this purpose more extensive powers must be obtained from the Legislature. To this end the second motion stated that:—

1. Simpler and less costly machinery should be devised and sanctioned by Parliament for enabling local authorities to put in force and carry out the provisions of the Housing of the Working Classes Acts. 2. That authority should be given to municipal corporations and other local authorities to acquire at its market value, by as simple and inexpensive a method as possible, and without any allowance for compulsory purchase, land for the present or prospective erection and maintenance of dwellings for the population to be displaced by the abolition of slum properties. 3. That any sinking fund required to be set apart for repayment of moneys borrowed for such purposes should apply to the cost of buildings only and not to land, and should be extended over a period of not less than 60 years, and that municipal corporations and other local authorities should be empowered to build such buildings in accordance with their own by-laws and not be required to satisfy the requirements of the Local Government Board.

Finally, a third motion was adopted to the following effect:—

That a joint representative committee be appointed by this Congress

for the purpose of adopting such measures as may be deemed requisite or expedient for bringing the several matters referred to in the first and second resolutions under the consideration of Parliament and for obtaining remedial and supplementary legislation thereon.

On the adoption of this motion the committee in question was at once appointed, and consisted of leading representatives from Glasgow, Edinburgh, Dundee, Aberdeen, London, Manchester, Liverpool, Newcastle, Sheffield, Dublin, Sunderland, Plymouth, and Leeds; the Lord Provost of Glasgow to act as secretary or convener.

This concluded the business of the Conference, but its members did not separate without first passing the usual complimentary vote of thanks to the Lord Provost and the Corporation of Glasgow for the useful initiative which they had taken in convoking the Conference and for the hospitality which they had bestowed on its members. Thus ended a memorable meeting. Perhaps it will be said that there were not many new proposals, ideas, or suggestions brought forward; but in any case what was only vaguely felt before has now been emphasised, explained, and rendered clear. All who assisted at the Conference have surely obtained a broader grasp and a more detailed knowledge of the subject. But there were some new suggestions, though these were not perhaps as numerous as might have been anticipated. Also, if the representative committee elected carry forward their mission with energy we may look forward to some practical results.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *Distinguished Visitors.*

THE renewal of the activity of the medical societies of the town during the coming session is evinced by the notices of meetings already sent out. These include the names of distinguished visitors who are announced to deliver addresses at various meetings. Thus on Oct. 18th Mr. Thomas Bryant will give an address and distribute the prizes at a meeting of the Clinical Board under the presidency of Mr. Bennett May. On Oct. 24th Mr. Victor Horsley will give an address on Medical Reform at a special meeting of the Birmingham and District Medical Practitioners' Union; and on Nov. 7th it is announced that an address on the Treatment of Wounds in War will be delivered by Mr. Watson Cheyne at the meeting of the Midland Medical Society. In their respective rôles it would be difficult to find authorities more entitled to a hearing, and none who will be more welcome to the audiences which gather to listen to them.

### *University of Birmingham.*

The inaugural meeting of the medical faculty took place on Oct. 1st, when the Dean, Professor B. C. A. Windle, received the guests to the number of about 400. The event was celebrated by proceedings of a social character at which the guests were entertained by a musical programme conducted by medical friends whose performances were much appreciated. The different museums—dental, anatomical, and materia medica—were thrown open and entrance was given also to the pathological and bacteriological departments. A demonstration of lantern slides and microscopical slides was given and the various arrangements for teaching in the most modern and approved forms were shown. The evening concluded with a pleasant reunion of old friends and the anticipation of a flourishing and successful session.

### *Defective Lamps.*

Accidents and injuries inflicted by the use of imperfect lamps constitute a good proportion of cases which come before the city coroner. At his court recently an inquest was held upon the body of a young man, aged 21 years, who met his death by a lamp of this kind being thrown at him as a missile. A quarrel occurred during a game of cards, and the lighted lamp was picked up by one of the group and hurled at the deceased. The lamp struck him on the shoulder and, breaking, enveloped him in flames. He was conveyed to the hospital and he subsequently died from the injuries he had received. The coroner in addressing the jury pointed out that this was another case of a lamp which had an earthenware container. In every case which had been before him where a lamp was concerned the vessel had been a china one. A lamp with a metal vessel could be obtained at a moderate price and it was much safer. In instances such as this the lamp would probably have gone out and would not have given rise to fire. How frequently this lesson is inculcated and how

often forgotten is a matter of common observation. The cheap lamps with pottery vessels are in common use among the poor and unless some legal restrictions are placed upon their sale we shall continue to hear of similar accidents which can safely be classed as preventable.

### *The Consultative Institute.*

In place of the door-plate so obnoxious to the orthodox profession for some months past the sign of "Ichabod" may be written over the portals of this recent venture. The door-plate has gone—the glory has departed. Conceived in misapprehension, developed in ignorance, and launched into life against the united voice and will of the profession, this inglorious institution has ebbd its life away ignominiously. It will be remembered that when the late occupant of this multifarious consultant scheme resigned his position it was loudly proclaimed that there would be no difficulty whatever in finding appropriate substitutes. The scheme was widened and enlarged. Proclamation was made as to the stability of its finances and the demand for its continuance. Advertisements were issued for consultants in various departments of medicine, surgery, and specialties. The result was but an echo of the professional voice which had emphatically demonstrated the futility and uselessness of the whole project. Whatever may have been the responses to the appeal made by the promoters time showed that they did not equal the ardent aspirations and confidence entertained by the prominent members of the administration. The institution has lapsed into a natural death, the effects have been sold, and its memory only remains as that of an unwarrantable and ill-judged attempt to exploit the services of an honourable and hard-working profession.

Oct. 15th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *Medical Faculty of University College, Liverpool: Opening Address by Dr. Oliver Lodge of Birmingham University.*

ON Oct. 12th Dr. Oliver Lodge, F.R.S., formerly professor of physics at University College and now the principal of Birmingham University, delivered the opening address to the medical students of University College and distributed the medals and prizes.<sup>1</sup> A thoroughly practical address was delivered to a brilliant assembly comprising the Lord Bishop of the diocese and other distinguished citizens. Before the close of the proceedings Professor Herdman unveiled a bust of Dr. Lodge executed by Mr. Allen, a well-known Liverpool sculptor, the likeness being a striking one.

### *Liverpool Medical Institution Dinner.*

The biennial dinner of the Liverpool Medical Institution took place on Oct. 12th. The gathering was a most successful one, the guests including the Lord Mayor, the Lord Bishop, and Dr. Lodge. About 120 gentlemen sat down to dinner.

### *The Mid-Cheshire Queen Victoria Memorial.*

Already £1396 have been raised towards the fund for the extension of the Victoria Infirmary, Northwich, which will be the mid-Cheshire memorial to Her late Majesty Queen Victoria. The Hospital Saturday Committee are making strenuous efforts to raise £200 towards the requisite £4000, and the employes of Messrs. Brunner, Mond, and Company have also warmly taken up the project.

### *Liverpool Country Hospital for Chronic Diseases of Children.*

In response to an appeal made by the honorary treasurer last week subscriptions amounting to £172 have just been announced. At present the committee are indebted to the West Kirby Convalescent Home for 20 beds, hence the appeal for funds to build an independent hospital at Heswall.

Oct. 15th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Cardiff Infirmary.*

MR. E. TENISON COLLINS, who has practised as a gynaecologist in Cardiff for some years, has been elected second honorary gynaecologist to the Cardiff Infirmary. Through the

<sup>1</sup> Dr. Lodge's address appears in full at p. 1021.

exertions and munificence of several prominent ladies in Glamorganshire it is now certain that the women's ward, which has been closed practically for more than a year, will be permanently supported by special subscriptions obtained in Cardiff and in the surrounding district. The dearth of junior practitioners is evidenced by the fact that, on the recent appointment of Dr. John Mooney of Openshaw, Manchester, to the position of assistant house surgeon he was the sole applicant for the post. At the meeting of the Board of Management of the infirmary held on Oct. 9th it was stated that the Cardiff workmen have only contributed during the present year £258 towards the funds of the institution, while the colliers, who in some districts have to support their own local hospitals, have contributed £498.

#### *British Dental Association.*

At the annual meeting of the South Wales and Monmouthshire branch of the British Dental Association held at Swansea on Oct. 10th Mr. H. J. Thomas in his Presidential Address drew attention to the large number of men who were refused admission to the army and navy on account of the poor condition of their teeth, and stated that a few years ago when a recruiting war-vessel visited Swansea 20 per cent. of the boys offering themselves for service were rejected for this reason. Mr. J. C. Oliver of Cardiff urged that information as to the proper preservation of the teeth should be disseminated by the State and that every child attending a public elementary school should have his or her teeth periodically examined during the whole period of school life. It was resolved to send a communication to the school boards and boards of guardians in South Wales and Monmouthshire reminding them that it was their duty to see that the teeth of children under their care were looked after and pointing out the injury that was being done to children by the loss of their teeth.

#### *The Anatomy Act at Bristol.*

At the meeting of the Bristol Board of Guardians held on Oct. 11th several members of the board strenuously opposed an application for permission to remove to the Bristol Medical School the bodies of persons who have died in the Eastville Workhouse without known relations or friends. Permission was ultimately given. It is a pity that those who seek to curtail opportunities for anatomical study do not take the trouble to ascertain the provisions of the Anatomy Act whereby it is impossible for any person to say that the body of any relative or of anyone he has known has been removed under the Act to a medical school.

#### *The Prevention of Consumption.*

The Gloucester, Somerset, and Wiltshire branch of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis has purchased a site of 50 acres at Winsley, near Limpley Stoke, upon which to erect an institution to be called the Royal Victoria Memorial Sanatorium. The site has been levelled and plans of the building have been prepared and at a meeting of the general committee of the branch held on Oct. 8th it was stated that of the £3176 already subscribed £2000 have been expended upon the purchase and preparation of the site and that a further sum of £9000 must be raised before the committee would feel justified in beginning to build.—The Urban District Council of Aberdare has decided to distribute from house to house the address which Dr. Isambard Owen delivered at the recent conference at Cardiff. The death-rate from phthisis in Aberdare in 1900 was 1.1 per 1000.

#### *Bristol Water-supply.*

Since the year 1846 the water-supply to the city of Bristol has been provided by a private company. With the experience of other large towns before them the city council has from time to time passed resolutions affirming the desirability of the supply being in the hands of the corporation, and about seven years ago instructed a committee to inquire as to the practicability of the purchase of the water undertaking. This committee reported to the council in 1898 that the waterworks company were not prepared to sell their property, and again reported on Oct. 8th last that after taking counsel's opinion they found that the corporation could not enforce any reduction of the present charges made by the company, and further that there was now a constant and efficient supply of water to the city. In the report of the medical officer of health for 1900, Dr. D. S. Davies states that as the company has power to make an annual charge for each closet flush very many outdoor closets throughout the city are dependent upon hand-flushing. The average daily supply of

water per head is calculated at about 22 gallons and no case of disease, says Dr. Davies, has ever been traced to its use. At present there are three storage reservoirs capable of holding 750,000,000 gallons and there will be completed early next year a fourth reservoir with a capacity of 1,700,000,000 gallons, when the reserve will be equal to nearly 250 days' supply. The water is obtained from springs in the triassic conglomerates and in the carboniferous limestone on the sides of the Mendip Hills at points distant from the city from five to 16 miles. A portion of the supply comes direct from springs to the town mains and is unfiltered; the stored water is filtered. In connexion with the new source of supply at Blagdon, in which the river Yeo is impounded, drainage schemes have been constructed by the waterworks company whereby the sewage of four villages will be treated on the septic tank principle.

#### *Superstition in Somerset.*

An inquest was held at Ilminster last week upon an old man who was found at the bottom of the stairs of his house with his neck fractured, and a verdict of "Accidental death" was returned. Evidence showed that he was considered to be a "witch doctor" and that farmers and females went to him to have the "evil eye" removed. It was stated that the old man had made a considerable sum of money out of his "patients."

#### *University College, Bristol.*

The inaugural lecture of the winter session of University College, Bristol, was delivered on Oct. 8th by the Bishop of Bristol on "The Responsibilities of Inheritance." Mr. P. J. Worsley presided and in his speech alluded to the fact that the College had now completed a quarter of a century of its existence. Mr. Worsley also stated that the present accommodation was inadequate for the work of the College, another block of buildings being required for enlarging the chemical and electrical engineering department, and on the medical side additional laboratory accommodation was required for bacteriological work. The estimated cost of this scheme was about £6000 and this sum it was hoped would be raised by the public spirit of the citizens of Bristol.—The annual distribution of prizes in connexion with the medical department of University College, Bristol, will take place on Oct. 25th. Sir Frederick Treves, K.C.V.O., C.B., will present the prizes.—The annual dinner of the Bristol Medical School will take place at the Royal Hotel on Oct. 25th. Dr. E. Markham Skerritt will preside and Sir Frederick Treves is to be the guest of the evening.

Oct. 14th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *The Carnegie Trust and the Payment of Class Fees.*

THE secretary of the Carnegie Trust has been authorised to send the following letter to the secretaries of the Scottish universities:—

2, St. Andrew-square, Edinburgh, Oct. 14th, 1901.

DEAR SIR,—It may be useful for the officials and students of your university to know some of the more general considerations which have guided the Executive Committee in deciding upon the claims of applicants for payment of class fees in the Scottish universities and in the extra-mural classes in Scotland, attendance at which is recognised as qualifying for graduation.

Three qualifications have been demanded. The applicant (1) must be over 16 years of age; (2) must be of Scottish birth or extraction, or must have given two years' attendance after the age of 14 at a school or institution under inspection of the Scotch Education Department; and (3) must be qualified by preliminary examination under the ordinances of the Scottish Universities Commission and the regulations of the Joint Board of Examiners to attend the classes for which payment of fees has been claimed.

In estimating the claims of applicants the committee have had under consideration the advisability of taking into account the financial aid which such applicants may be at present receiving from bursaries or other sources. They are of opinion that the bodies granting such aid are the proper judges of the intention of their beneficiaries and the needs of their beneficiaries.

It has been impossible in the circumstances of inaugurating the work of the trust to foresee all the particulars which for the purposes of the committee are required from applicants. This is only referred to in order to make it clear that the details of the present arrangements may be reconsidered in the light of further experience.

Two points may be mentioned. In the first place, the committee have resolved that they must insist in all cases on proof of the capacity of the applicants. It is obvious that in fairness the standard should so far as possible be the same for all, but this is not easily attainable under the existing regulations for the preliminary examinations of the universities. The committee have for the present followed the standards of preliminary examinations for the various faculties laid down by the Universities Commission.

In the second place, it is the duty of the committee to satisfy themselves of the conduct and progress in the studies of students receiving benefit from the fund. It has been, of course, impossible to enter on this occasion upon an investigation of the career of all the applicants. Many of them have already attended classes for several sessions. But it is proposed to make it a condition that every student whose fees are paid must submit to the committee a report or certificate from the professor or lecturer whose class he has attended establishing that his use of the opportunities afforded him has been satisfactory. Many applicants have applied for a large number of classes. In some cases the committee have thought it necessary to restrict demands for classes obviously in excess of what can be usefully taken.

On these points the committee would welcome the opinion and co-operation of the universities.—I am, yours truly,

W. S. M'CORMICK.

#### *Ruchill Fever Hospital, Glasgow.*

The first report of the recently opened hospital for infectious diseases, by Dr. A. Johnston, the physician superintendent, was presented to the Glasgow Town Council on Oct. 14th. It covers the period of time from Sept. 10th, 1900, to May 31st of the present year. The original plan of organisation was to close the hospital in Kennedy-street and to draft the staff to Ruchill. Owing to the small-pox epidemic this proposal had to be abandoned and the two hospitals were used for a period of nearly six months to accommodate all infectious cases other than small-pox, the latter being sent to Belvidere. The number of cases admitted to the two institutions during the year ending May 31st, 1901, was 3615. The mortality, it is gratifying to note, was only 6·8 per cent. Dr. Johnston draws special attention to the remarkably low death-rate in the cases of scarlet fever—viz., 2·8 per cent. In discussing the report Councillor Maxwell claimed that a large measure of credit for these satisfactory returns was due to the corporation for their enterprise in improving the housing conditions in various parts of the city. The necessity for constant official protection of the public health was well illustrated by a recent incident in which the carcass of an ox consigned from Ireland to a meat salesman in Glasgow was after examination found to be affected with anthrax. So far no prosecution has taken place, but the matter, it is to be hoped, will not be allowed to rest.

#### *Suspected Case of Plague in Glasgow.*

Some not unnatural anxiety has been created during the past week by the rumour that a case of plague had been removed from a vessel in the harbour. It appears that a Lascar seaman was found on one of the steamships lying in the Govan Docks with a somewhat mysterious illness, and that by the advice of the medical authorities he was removed to the local hospital for infectious diseases. Though technically both the vessel and the patient were outside the sanitary jurisdiction of Glasgow it was wisely and properly decided to ask the opinion of Dr. Chalmers. The mystery is not yet fully cleared up, but Dr. Chalmers reports that there is no evidence to warrant the assumption that the case is one of plague.

#### *Faculty of Physicians and Surgeons, Glasgow.*

Mr. George Burnside Buchanan, B.A. Cantab., M.B. Glasg., having passed the necessary examinations, has been elected a Fellow of the Faculty.—At the recent celebrations in connexion with the eightieth birthday of Professor Virchow an address of congratulation on behalf of the Faculty was presented by Lord Lister, F.R.S.

#### *St. Andrews University.*

The winter session was opened on Oct. 8th with an address by Principal Donaldson in which the opinion was expressed that neither the Government nor the public were alive to the national importance of increasing and extending the range and efficiency of university education. He hoped that by means of Mr. Carnegie's great generosity the Scottish universities would now be able, at least in the scientific and modern departments, to take a great step forwards, more especially in the development of original and research work. Regarding the payment of students' fees he considered that the Scottish ideal of securing the chance of a university education for everyone capable of utilising it was a sound one and he cordially accepted the conditions which the trust has already defined. The students of the colleges at St. Andrews and at Dundee have decided to invite Mr. Carnegie to come forward as a candidate for the position of Lord Rector of the University. At a meeting of the Senatus Academicus on Oct. 12th Mr. R. B. Haldane, K.C., M.P., was appointed lecturer on natural theology under the conditions of the Gifford Trust. The duties consist of the delivery of some 10 lectures during the session and the emoluments

amount to between £500 and £600. The lectureship is held for two years.

Oct. 15th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Nursing in Irish Workhouses.*

DR. COX, in his inaugural address at St. Vincent's Hospital, dealt with the subject of nursing in Irish workhouses and advocated strongly the cordial support of the Local Government Board in their recent efforts to secure efficient training for nurses. He showed that it was essential that the education of nurses should be carried out in the large and fully equipped clinical hospitals of the metropolis, instead of being relegated to provincial and non-teaching institutions. The *Irish Times* in a leading article on Oct. 9th said that Dr. Cox had done a great public service in making the question of the proper training of nurses the subject of his able address. Dr. Edward Thompson, M.P., while advocating the full and efficient training of nurses, holds that they could be best trained in suitable provincial hospitals previously inspected and certified as to their efficiency by the inspectors of the Local Government Board. A long letter on the subject from him appeared in the *Irish Times* of Oct. 15th.

#### *Irish Workhouse Association.*

A committee meeting of the above was recently held at 22, Lincoln-place, Dublin. The attendance included Lord Monteaigle (president), Lady Monteaigle, Mrs. Haslam, Dr. Katherine Maguire, Mrs. Leonard, R.D.C., Dunsany; Dr. Moorehead, Cootehill; Mr. W. M'Murrough Kavanagh, and Mr. Charles Eason. The chief matters considered by the meeting were the condition of the sane epileptics at present in Irish workhouses and the question of nursing in Poor-law infirmaries, with special reference to the revised general order recently issued by the Local Government Board. An announcement was received from the Belfast branch of the association to the effect that it is intended to hold a conference in that city early next month for the purpose of considering several important matters in connexion with Irish Poor-law. It is hoped that the conference will be well attended, and that it will be productive of much good.

#### *The Meath Hospital and County Dublin Infirmary.*

The address introductory to the one-hundred-and-forty-ninth session of the Meath Hospital was delivered on Oct. 14th by Mr. William Taylor, surgeon to the hospital, in the presence of a large assemblage. The subject dealt with was Modern Progress in Surgery.

#### *The Royal Victoria Hospital, Belfast.*

The City Corporation of Belfast are about to promote an "omnibus" Bill in the next session of Parliament, in which, amongst other matters, provision will be made for the council having authority to make a further grant of six acres for the purposes of the Royal Victoria Hospital. This is to be provided from the old asylum grounds (owned by the corporation) in order to make the institution more perfect.

#### *The Health of Belfast.*

The report of the medical officer of health presented to the City Corporation of Belfast on Oct. 1st showed that during the past month 679 cases of zymotic disease have been notified—viz., 374 typhoid fever, 208 simple continued fever, 32 erysipelas, 27 diphtheria, 25 scarlet fever, seven membranous croup, and six puerperal fever. There were 159 deaths registered from zymotic diseases, 64 from phthisis, and 56 from diseases of the respiratory organs. The total annual death-rate was 22·0. The regretful features of this alarming report are: (1) that there is a considerable increase in the number of notifications of zymotic diseases; (2) that the outbreak of typhoid fever still continues and now the disease seems to be prevalent in all the districts of the city, and, unfortunately, the deaths therefrom are also more numerous; and (3) that the cases of diphtheria have also increased. It is satisfactory to find some crumbs of comfort inasmuch as the deaths from measles number seven as compared with 19 in the last report, and scarlet fever (apparently now a very mild zymotic in Belfast) caused only one death in the month. In the discussion which followed attention was drawn to the delay in changing from dry- to water-closets in the small houses in its effect as regards outbreaks of typhoid

fever, to the importance of inspection of butter-milk, the prevention by milk-vendors of the mixing of milk, and the supervision of ice-cream vendors. Councillor J. D. Williamson, M.D. R.U.I., advocated the inclusion of measles and phthisis in, and the elimination of continuous fever from, the notifiable diseases.

#### *The Belfast Board of Guardians.*

At a meeting of this body on Oct. 1st it was decided to erect a nurses' home in connexion with the fever hospital to accommodate 36 nurses. A suggestion from the Infirmary Committee to improve the dietary of the nurses and medical officers and apothecary was rejected. It is hard to understand the policy of a board who are anxious to expend £13,000 in building a new board-room and offices and who at the same time decline to make the dietary of their medical officers and nurses (13 have had typhoid fever) equal to that of any third-class hospital in England. All the long discussion was over the question of giving each hospital nurse one chicken instead of one between four, and of substituting 10 pints of milk instead of eight, a pound of pork (in case they did not take the equivalent in chicken), a quarter of a pound of cheese per week, half a pound of oatmeal, and half a pound of jam or marmalade, with pickles, butter, and salt, for the resident medical officers. Nothing is in the long run worse than this "penny-wise-and-pound-foolish policy."

#### *St. John Ambulance Association.*

The annual meeting of the Belfast branch of this association was held on Oct. 11th. It was reported that during the year 18 first-aid classes were held and were attended by 410 pupils, and four nursing classes which were attended by 67 pupils—in other words, there were 22 classes attended by 477 pupils. A new feature had been the instructing of men in "home nursing of the sick" and 16 certificates were granted to members of these classes. The work of the firemen who form the Belfast division of the St. John Ambulance Brigade was highly appreciated and they received 1867 calls. The distance traversed by the ambulance carriages was 4487½ miles, or an average of two and a half miles per single journey. Financially there is a small balance to the credit side of this Belfast branch.

#### *Opening of the Winter Session in the Belfast Medical School.*

The present winter session (1901-1902) of the Belfast Medical School began on Oct. 15th when the introductory address at the Royal Victoria Hospital was given by Dr. Robert Campbell, one of the assistant surgeons. After welcoming the students and giving them some admirable advice, Dr. Campbell said that he regretted the present unfortunate condition of university affairs in Ireland. Apparently every 20 years or so that question was thrown into the crucible by various Governments and he deplored the apparent determination on the part of some of the present Ministers to yield to sectarian clamour. Dr. Campbell then proceeded with his address on the Limitations of Surgery, in which he showed the lines upon which further original work was needed. He illustrated his remarks by reference to sepsis, tuberculosis, and cancer, and said that they wanted further information as to the chemistry of the blood in these diseases and as to the general constitutional condition present. Dr. Campbell's address, which was full of humour, sound common-sense, and apt illustrations, was loudly applauded at its conclusion by his colleagues and the large audience of students present. Classes began at the College in the afternoon.

#### *Monaghan District Lunatic Asylum.*

At the monthly meeting held on Oct. 10th it was reported that there were 465 male patients in the institution, while the statutory accommodation was for 362—that is, 103 male patients in excess of the limit, a condition of overcrowding prejudicial to the health of the patients as well as to their recovery. It was decided to ask the guardians of the workhouses in Cavan and Monaghan if they would receive harmless certified lunatics, and if so, how many, in case £20 per annum were paid for the maintenance of each lunatic. The Inspectors of Lunacy and the county council were also asked to approve of this arrangement in view of the large expense that the extension of the asylum would involve.

#### *The Armagh Guardians and the Local Government Board.*

At a meeting of this Board held on Oct. 1st a letter was read in reply to the resolution of the guardians calling upon the Local Government Board to withdraw their allegations against the medical officer of the union (see THE LANCET, Oct. 5th, p. 947), and it was decided unanimously that it

should be marked "read," the chairman observing that it was the proper way to treat such a letter.

Oct. 15th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Distribution of Antimony in the Organism after Ingestion.*

At the first meeting of the Academy of Medicine held after the holidays M. Pouchet read a very interesting paper upon some experiments which he had made upon animals with a view to find out how antimony would be found distributed in the organism in cases of chronic poisoning, especially as compared with the distribution of arsenic. The results were notable from a medico legal point of view. A rabbit weighing 1095 grammes was fed for 50 days upon a diet in which were contained 30 meals to every one of which had been added five milligrammes of tartar emetic. The animal thus received in all 150 milligrammes of the salt corresponding to 54 milligrammes of antimony. The rabbit was killed and upon examination the antimony was found to be distributed chiefly in the digestive apparatus, while the skin, the fur, and the nervous system—that is to say, the tissues in which arsenic is most appreciably found—contained a mere trace of antimony. In other animals it was found that the addition of arsenic to the antimony, even in a very small proportion, affected the skin and the nervous system at an earlier date and more seriously than pure arsenic. In those animals which died from mixed poisoning the brain, the muscles, and the spinal cord, together with the liver, contained arsenic and very little antimony. The skin and the fur contained a large quantity of arsenic and more antimony than the tissues previously mentioned, while the digestive tract contained but little arsenic and the greatest proportion of antimony. If bromide of potassium were administered together with the poisons both the symptoms of poisoning and the distribution of the poison were considerably modified.

#### *The Plague at Marseilles.*

There has been no new case of plague among the passengers of the *Senegal*, but complaints continue to be made about the very unsatisfactory condition of the lazaretto at Frioul. It affords hardly any shelter from the weather and neither doors nor shutters fit. The sleeping-rooms are so damp that the plaster is falling off the ceilings, and the walls and the floor are in a terrible condition of dirt. Complaints come from all sides, one result of which has been that the corridors have been swabbed out with carbolic acid. The cooking and table arrangements leave much to be desired, and, as might be expected, it is very difficult to get cooks or servants, for they are all afraid of infection. Food is sent in from Marseilles and given to the unfortunate people in the lazaretto through a grating which is placed at a distance of three metres from a second grating where one of the sanitary officials takes it in.

#### *The Accident to Dr. Calmette.*

I have already acquainted your readers<sup>1</sup> with the main facts as to the accident to Dr. Calmette, the Director of the Pasteur Institute, who was dangerously bitten in the hand by one of his rattlesnakes while he was making experiments. Dr. Calmette immediately inoculated himself with his anti-venomous serum and the immediate results were, apparently, exceedingly satisfactory. Since then, however, although the wound had almost entirely healed, local complications occurred in its vicinity and Dr. Calmette has unfortunately had to undergo amputation of the ring finger of his right hand.

#### *A Revolver Bullet Extracted from the Surface of the Lung.*

At a recent meeting of the Society of Surgery M. Loisin reported the case of a soldier who had been brought into the hospital at Val-de-Grâce. The wounded man had been shot with a revolver, the bullet of which had penetrated the chest at the level of the outer end of the clavicle. By radiography it was perceived that the bullet lay in the second intercostal space, some centimetres from the edge of the sternum and at a depth of from two to three centimetres from the surface. The second intercostal space was incised, but the bullet could not be discovered, despite repeated probing with a

<sup>1</sup> THE LANCET, August 31st, 1901, p. 622.

very fine trocar. Some little time afterwards, however, the x rays were again brought into use by means of the Contremoulins apparatus, and it was seen that the bullet was where it had been seen before. Another incision was made, the pleura was opened, and on the lung retracting it was found to be easy to seize the bullet with a pair of forceps and to remove it, since it was only covered by a very thin layer of pulmonary tissue. The bullet was a Mauser rifle bullet of a diameter of seven millimetres, and the wounded man made a perfectly uneventful recovery.

Oct. 15th.

## ROME.

(FROM OUR OWN CORRESPONDENT.)

### *The Plague at Naples.*

ONLY one fresh case of plague has been reported at Naples during the past week and none from any other part of Italy. The new case was in a girl, 13 years of age, and is the first attack in a female. Death took place two days after the patient's removal to Nisida, the symptoms having been virulent from the first. Another death occurred there on Oct. 9th of a man who had been seized with the disease on Sept. 21st, and had therefore had an illness of fully 18 days' duration. There appear to have been altogether 21 cases, with seven deaths, since the commencement of the outbreak up to the present time, but as yet no official statistics are available in regard to this. The greater number of the "contacts" have been set at liberty, but according to the terms of the Venice Convention the occurrence of the fresh case prevents the authorities from giving the port "libera pratica" until 10 days after its isolation. The required period will not thus elapse before Wednesday, Oct. 16th. There are now at Nisida only three persons actually under treatment, 14 convalescent, and 36 still under observation. As a proof that the outbreak is regarded as practically extinguished the announcement is made that the King and Queen, with the infant Princess Jolanda, will arrive at Capodimonte not later than the 25th of this month.

Oct. 13th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

### *The Bubonic Plague.*

TWO suspicious cases, one fatal, of bubonic plague have occurred in Sydney and there has been another fresh case in Brisbane, the patient being a seaman on a steamer trading between Brisbane and Townsville.

### *Health of Sydney.*

Dr. W. G. Armstrong, health officer of the metropolitan district of Sydney, has furnished a report on the health of the city and the work of the sanitary department for the quarter ending June 30th. On the whole the conditions of health in the city were improving. House-to-house inspection had shown that the poorer classes were badly domiciled and careful and prolonged investigations showed that defects of construction and neglect of repairs leading to gross insanitary conditions of dwellings were more common in the poorer quarters of the city than was believed to be the case even three months ago. Whole terraces of houses were found to be dangerously damp and unhealthy from want of proper damp courses or absence of ventilation beneath the floors. The systematic inspection of common lodging-houses had brought to light some very objectionable and insanitary conditions. Unsuccessful attempts had been made to abate the "expectoration nuisance." Disinfection of dwelling-houses where infectious diseases and consumption had occurred had been carried out as far as practicable. Scarlet fever, diphtheria, and typhoid fever all showed an increase on the returns for the last quarter. The outbreak of cerebro-spinal fever had abated, only one death being recorded.

### *Increase in Cancer.*

A deputation recently waited on the Premier of South Australia to request him to provide accommodation for the care and treatment of cancer patients. It was pointed out that the Home for Incurables had done all it could to deal with these cases, but the increase in the disease had been such that this institution could no longer

accommodate the cases requiring treatment and a cancer hospital was necessary. It was stated that cancer was largely on the increase all over Australia. The Premier said that he would endeavour to induce the Charity Commissioners to devote some of the funds at their disposal to the erection of a cancer ward in the hospital grounds.

### *The Notification of Consumption.*

The Board of Public Health of Victoria has decided to declare consumption an infectious and consequently a notifiable disease. The chairman of the Board (Dr. D. A. Gresswell) has long been an advocate of notification in the case of pulmonary tubercle and recommended the measure in an address in 1899. He has explained that the purpose of notification is mainly educational in order that patients and their friends may be furnished with proper instructions to prevent the spread of the infection and that the ventilation and drainage of their houses may be seen to and disinfection carried out when a patient leaves. A number of medical men have opposed the action of the Board, pointing out that it is the duty of the health authorities to see to the ventilation and drainage of all houses, not only those inhabited by consumptives; that the medical attendant can see that proper directions are given to the patient and his friends; that notification without its natural corollary of segregation, as in leprosy, is practically futile, and no one at present suggests segregation. On the other hand notification may cause harm to the patient who will be, so to speak, branded and may lose occupation in consequence.

### *Hospital Affairs.*

At the last meeting of the directors of the Prince Alfred Hospital, Sydney, correspondence was received from the Executive of the Hospital Saturday Fund intimating that in future, in the case of patients accepted for admission who are "industrial subscribers" to the Hospital Saturday Fund, and properly recommended, the Fund would guarantee payment to the hospital at the rate of 4s. per day. It was resolved that the Executive of the Fund be informed that the hospital could receive no recommendations which would confer upon patients the privilege of being admitted to the wards, and that the only considerations which governed admission were the suitability of the cases medically and the financial means of patients, the hospital being primarily for destitute persons. It may be explained that "industrial subscribers" to the Fund are employes who contribute regularly every week out of their earnings some small sum from (generally) a penny upwards. Originally the Fund was started with the object of financially assisting the hospitals in their legitimate work of giving medical attendance to the destitute sick. But in all the hospitals the practice is extending of exacting payment from patients for their maintenance and according to their means, and in Sydney if an applicant is unable to contribute he has to get an order from the Government medical officer after making a declaration that he is destitute. Then the Government pays the hospital for his maintenance at the rate of £1 a week. The proposal of the Fund Executive would enable individual patients to escape making a declaration and also to escape individual payment, and is practically constituting the Fund into a club for those in receipt of regular wages to enable them to secure hospital treatment, they being a class who ought to receive medical treatment through the means of friendly societies or as private patients of outside medical men.—A deputation from the Sydney Hospital has waited on the Minister of Works to ask him to reserve permanently the site of the Moorcliff Eye Hospital, which is within the Darling Harbour resumption area, and now vested in the Harbour Trust. The Minister replied that the proposed scheme of reconstruction in the locality would probably render the site less suitable for a hospital, and he thought that the committee should look out for a more suitable place. He would consult with the Harbour Trust and if their proposals would not clash with the hospital he would fall in with the views of the deputation.—At the annual meeting of the subscribers to the Women's Hospital, Melbourne, a much-debated question was brought up for discussion—viz., whether married women should be distinguished from single women (in the maternity department). Since the foundation of the hospital married women had been distinguished by the prefix "Mrs." on their bed-tickets, but objections had been raised to the custom. The meeting decided that the existing practice should be continued until separate wards can be made available for married and unmarried patients. The report for the past

year showed that 1778 in-patients had been treated—1359 in the midwifery department. The receipts had been £6507 and the expenditure £7028. The committee regretted the inability to accommodate large numbers of patients constantly seeking admission and hoped that as the result of a special appeal they would be able next year to erect much-needed additions to the wards.

#### *Proposed Dental Hospital, Sydney.*

For four years negotiations have been carried on between the Sydney University and the Sydney Hospital with regard to establishing a clinical dental department at the hospital. At the last meeting of the University Senate the Dean of the Faculty of Medicine reported that the proposed arrangements had fallen through as it was found impossible to accommodate a dental school on the site of the hospital. The Senate resolved to establish an independent university dental school and hospital, and a flat at the corner of George-street and Bathurst-street has been leased for the purpose and is being fitted up as rapidly as possible. Many of the Sydney dentists are opposed to the hospital as proposed and want to have a dental hospital managed entirely by the dental profession and not by the University authorities as is done in Melbourne.

#### *The Dentists Act, New South Wales.*

The Dental Board of New South Wales has made a number of regulations under the Dentists Act. Among them it is stated that the following are the certificates, diplomas, membership degrees, licences, letters, testimonials, titles, statutes, or documents which will be recognised by the board, under section 12 of the Dentists Act—viz., Licentiate in Dental Surgery of the Royal College of Surgeons of England, Licentiate in Dental Surgery of the Royal College of Surgeons of Edinburgh, Licentiate in Dental Surgery of the Faculty of Physicians and Surgeons of Glasgow, Licentiate in Dental Surgery of the Royal College of Surgeons in Ireland, Licentiate in Dental Surgery of a University in Australia or other British possession, degree of Doctor of Dental Surgery or Doctor of Dental Medicine, conferred by a school, which is either a member of the National Association of Dental Faculties of the United States of America or the diploma of which is recognised by the State Dental Board of the State under whose charter it works, the licence or diploma of any other legally qualified dental school or dental board the certificate of which is granted after not less than three years' study or five years' practice of dentistry and satisfactory examination in the following subjects—viz., anatomy, physiology, histology, bacteriology, pathology, therapeutics, chemistry, metallurgy, materia medica, operative dentistry, prosthetic dentistry, hygiene, and orthodontia. It is further provided that the Dental Board shall from time to time hold, or cause to be held, examinations in theory and practice of persons being registered as dentists and shall grant certificates to persons being registered as dentists and shall grant certificates to persons passing any such examination. The board shall admit to such examinations any person desiring to be examined who has previously paid a fee of £5 5s. and has satisfied the board that he is a person entitled to submit himself for examination, provided that a subsequent examination may be allowed on payment of a further fee of £3 3s. and on such conditions as the board may determine.

#### *Medical Libel Action.*

Dr. Merrillees, resident medical officer of the Ararat Hospital, recently brought an action against Dr. Palmer and Mr. Hayman of Ararat for £2000 damages for alleged libel. It is satisfactory to find that the case has been settled out of court, but it involved some interesting points in medical ethics. Dr. Merrillees gave a public lecture on Alcohol in which he denounced those who ordered its administration in disease, and cited the case of a patient in the Ararat Hospital who nearly died after alcohol had been given by his locum-tenent but recovered when treated by Dr. Merrillees without alcohol. Dr. Palmer and Mr. Hayman then declined to meet Dr. Merrillees in consultation and also inserted a notice in the local paper to this effect. This notice constituted the alleged libel.

#### *Cerebro-Spinal Meningitis.*

The *Intercolonial Medical Journal of Australasia* for August contains a report of a series of seven cases of cerebro-spinal meningitis occurring in the Children's Hospital, Melbourne, by Dr. W. C. Mackenzie, which is interesting from the extreme rarity of the disease in Australia. In

two of the cases intra-cellular diplococci were found in the fluid obtained by lumbar puncture, a procedure found to be of value for the relief of symptoms as well as for diagnostic purposes. Only one of the cases was fatal with characteristic post-mortem appearances.

Sept. 10th.

## Obituary.

EDWARD HARRIMAN DICKINSON, M.D. EDIN.,  
F.R.C.P. LOND.

MUCH regret was felt by the medical profession generally in Liverpool, as well as by a large circle of lay friends, at the announcement of the death in his fifty-ninth year of Dr. Edward H. Dickinson, which took place on Oct. 10th. He had suffered for a considerable period from cardiac asthma, the attacks of dyspnoea at times being very distressing. Dr. Dickinson studied medicine at the University of Edinburgh and at St. George's Hospital, London. He graduated as M.D. at the University of Edinburgh in 1876, obtaining the gold medal for his thesis. He was elected a Fellow of the Royal College of Physicians of London in 1880, at the early age of 38 years. He was formerly lecturer on comparative anatomy and zoology at University College, Liverpool, and was honorary physician to the David Lewis Northern Hospital for upwards of 30 years—an appointment which he resigned in the spring of this year owing to failing health. Dr. Dickinson was a man of rich and varied accomplishments. Educated at Cheltenham and Trinity College, Oxford, he started the race of life well equipped to encounter its difficulties and to appreciate its enjoyments. Naturally of a refined taste, he took a keen interest in the fine arts and developed a critical discrimination in the choice of pictures. His love of all manly sports, especially on the moor and at the river-side, aroused in him an intelligent interest in all that appertained to country life. His sympathy with suffering, his generous nature, his staunch friendships, and his love of truth endeared him to all his friends, who sincerely lament his premature decease. He was twice married and leaves a widow and three children to mourn their loss. The interment took place on Oct. 15th, at Lamplugh in Cumberland.

THOMAS VINCENT JACKSON, F.R.C.S. EDIN., J.P.

By the death of Mr. T. Vincent Jackson the medical profession has lost a prominent and honourable member and the town of Wolverhampton a spirited and high-minded citizen. Failing somewhat in health for some months past he finally succumbed to pneumonia after a brief illness, and died on Oct. 12th at his house in Waterloo-road. Born in London Mr. Vincent Jackson was educated at a private school at Brighton and afterwards at King's College, London. Later he entered as a medical student at University College and Hospital where by his industry and assiduity he obtained due scope for his intelligence and was rewarded by various posts in the teaching departments. He was appointed demonstrator of anatomy in the school, subsequently house surgeon at the hospital, and assistant in the ophthalmic department. Subsequently he became private assistant to Mr. Richard Quain, but his health failing he relinquished his London prospects and settling at Wolverhampton was elected a surgeon to the Wolverhampton and Staffordshire General Hospital. To this institution he devoted his services unremittingly to the time of his death. As a surgeon Mr. Vincent Jackson held a high position in the profession, his interest in this branch of the profession obtaining for him more than a local reputation, more particularly by his contributions to the study of lithotomy, perineal operations, and colotomy. He was one of the founders of the Pathological and Clinical Section of the Birmingham and Midland Counties Branch of the British Medical Association and in 1889 was elected president of the branch. On that occasion he delivered an address on the history of the medical profession down to the time of the Victorian era, closing a lucid and interesting sketch with the sound advice of a man who knew and felt what he uttered with the memorable—

Improve the best, so shall your sons  
Better what you have bettered once.

Straightforward and sincere in his judgment he ever sought

to advance the interests of the profession and to maintain its dignity and honour. A somewhat impulsive manner, the outcome of an ardent temperament and sense of personal conviction, made him at times misunderstood, though those who knew him best felt that his heart was directed right. As a citizen Mr. Vincent Jackson was fully alive to his duties and responsibilities. Taking an active part in public affairs he was first a town councillor, then elected mayor in 1886, afterwards becoming an alderman in the city of his adoption. As a magistrate for the borough and for the county of Stafford he exercised his functions impartially and with care. As a type of a high-minded citizen, a firm friend, and an indefatigable worker in his profession he has left a noteworthy example to others. He died at the age of 67 years, leaving a widow to mourn her loss.

**DEATHS OF EMINENT FOREIGN MEDICAL MEN.**—The deaths of the following eminent foreign medical men are announced:—Dr. Galvanis, Professor of Surgery in the University of Athens and Surgeon to the Evangelismos Hospital.—Dr. Max Freudweiler, Assistant Physician for Hydrotherapy and Gymnastic Methods in the Zürich University Clinic.—Dr. H. von Wyss, Professor of Forensic Medicine in Zürich, at the age of 54 years.

## Medical News.

**UNIVERSITY OF CAMBRIDGE.**—At a Congregation held on Oct. 10th the following degrees in Medicine and Surgery were conferred:—

*Doctor of Medicine.*—Charles Samuel Myers, Gonville and Caius.  
*Bachelor of Medicine and Bachelor of Surgery.*—Harold Walker, King's; John Percy Lockhart Mummery, Gonville and Caius; John Bradford, Emmanuel.

Dr. L. Humphry has been appointed Assessor to the Regius Professor of Physic. In the present term the first M.B. examination will begin on Dec. 9th, the second on Dec. 9th, and the third on Dec. 10th. A paper explaining the changes in the third M.B. examination, which will come into effect next year, has been prepared by the Registry and may be had by students on application.

**FOREIGN UNIVERSITY INTELLIGENCE.**—*Berlin*: It is intended to establish a Propædæutic Medical Clinic in the Moabite Hospital with Dr. Renvers and Dr. Goldscheider as professors.—*Breslau*: Dr. Lesser has been appointed Extraordinary Professor of Forensic Medicine.—*Caracas*: Dr. J. de Villegas Ruiz has been appointed to the chair of Clinical Medicine and Pathological Anatomy.—*Königsberg*: Three of the professors of the medical faculty have refused to allow female students to attend their lectures, so that it is practically impossible for ladies to attempt to carry on medical study in this university.—*Sienna*: Dr. A. Andrucci has been recognised as *privat-docent* of Operative Medicine and Dr. E. Modigliano as *privat-docent* of Pediatrics.

**LOWESTOFT HOSPITAL.**—The annual meeting of the governors of this hospital was held on Sept. 2nd under the presidency of the Earl of Stradbroke. The report stated that, exclusive of £552 10s. donations placed to the capital account, the income had been £1799 and the expenditure £1684. At the close of the account there was a balance to the credit of the treasurer of £195. The capital account had been increased by the generous gift of £500 from the officers and men of H.M.S. *Hearty*, which sum, together with a cot complete in every way, was handed to the trustees in November last. A life donation of £52 10s. has been received from Mr. George Jewson and placed to the capital account.

**SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.**—A quarterly court of the directors was held on Oct. 9th, Mr. Christopher Heath, the President, being in the chair. Two new members were elected and the death of a member was reported. There were no fresh applications for grants. The death of a widow was announced who had been in receipt of grants since 1882 and had received £1084 10s. from the society, her husband having paid £28 as subscriptions. Applications for renewal of grants were read from 51 widows, 13 orphans, and five

recipients from the Copeland Fund, and it was resolved that £1168 should be distributed among them at the next court. It was determined to make a Christmas present to the widows and orphans on the fund, the sum of £569 to be divided among them, thus disposing of the surplus income. The expenses of the quarter were £66 5s.

**ROYAL COLLEGE OF SURGEONS IN IRELAND: FELLOWSHIP EXAMINATION.**—The following candidates having passed the necessary examination have been admitted Fellows of the College:—Mr. J. M. Falkiner (Assam, India), Mr. G. A. Gunton (London), Mr. W. H. Langley (Nigeria, West Africa), and Mr. J. R. Macnamara (Assam, India).

**BRISTOL GENERAL HOSPITAL.**—Dr. A. J. Harrison, physician to the newly formed dermatological department of the Bristol General Hospital, will now be able to carry out the Finsen treatment for lupus, Sir William Wills having undertaken to defray the cost of the process for one year.

**NORTH SURREY DISTRICT SCHOOL, ANERLEY.**—There was a general muster of the officers and staff on Oct. 8th, when Mr. C. Bray (the superintendent), supported by Mr. H. J. Prangle (the medical officer), Mrs. Marsland (the matron), and others, made a presentation of a satinwood wardrobe and a purse of gold to Mr. and Mrs. Orpin, who are retiring on pension from their position at the schools. They have been at the lodge about 17 years. Mr. and Mrs. Walter Overton were appointed their successors.

**NURSES' HOME AT ALTRINCHAM.**—A new Nurses' Home in connexion with the Altrincham Provident Dispensary and Hospital was opened on Oct. 12th by the Duchess of Buckingham and Chandos. The accommodation in the hospital for the nursing staff being inadequate a convenient house close to the hospital was purchased at a cost of £1500. The whole expense of acquiring and fitting up the home has amounted to £3400. Towards this the trustees of the Altrincham Workhouse Charity have allocated the sum of £2000, and the remainder has been paid out of the reserve fund. The present buildings were erected in 1870 and in the following year the number of in-patients admitted was 28, while last year the number was 301.

**THE FORTHCOMING ELECTION OF DIRECT REPRESENTATIVES.**—We learn that Mr. George Brown, who seeks re-election, and Mr. George Jackson, F.R.C.S. Eng., who is also a candidate for a seat on the General Medical Council, will address the members of the Midland Medical Union, of which Mr. J. Goodwin Shea, J.P., of Chesterfield, is president, at their annual meeting to be held at the Masonic Hall, Nottingham on Wednesday, Oct. 23rd. At a meeting of the Medical Guild, Manchester, held on Oct. 16th, it was decided to invite Mr. Horsley and Dr. Woodcock to address a meeting at the Palatine Hotel, Manchester, on the 23rd inst., and Mr. George Brown and Mr. George Jackson to a meeting at the same place on the 24th inst. Dr. Glover to be invited to address either meeting as he shall prefer.

**THE NATIONAL REGISTRATION OF PLUMBERS.**—The Mayor of Derby, in presenting certificates of registration to several master and operative plumbers at the Guildhall, Derby, on Oct. 12th, said that the objects of the national registration of plumbers were such as to commend themselves to every thoughtful person. For some years the organisation had been seeking powers in Parliament to legalise the present voluntary system of registration to enable those employing plumbers to be satisfied that they were employing thoroughly efficient workmen. Those objects appeared to him to be thoroughly laudable, and he sincerely hoped that they would be achieved. As the health of people depended so much upon the plumbers, it was obviously necessary that the work should be carried out by competent and practical men. Alderman Richard Hind, mayor of Stockton-on-Tees and Renter Warden of the Plumbers' Company, referred to the work of the organisation, particularly with regard to the technical education of young plumbers. The object was to get more carefully educated and well-trained workmen through the medium of the technical classes. Sir Thomas Rowe, M.P., in expressing his sympathy with the objects, stated that he had been closely connected with the building trade all his life and was fully alive to the importance of plumbing work as affecting public health. He was entirely

in sympathy with the Plumbers' Registration Bill and would support the measure on all occasions.

**BARKER ANATOMICAL PRIZE.**—This prize of 20 guineas, open to all medical students of the United Kingdom, has been awarded to Miss Susan Forster Dickson, a student of the Royal College of Surgeons in Ireland.

**DONATIONS AND BEQUESTS.**—The late Mr. Thomas Kincaid Hardie, of 3, Hyde-park-terrace, London, has bequeathed to the Rothesay Victoria Hospital a sum of £500.—The committee of the North London Hospital for Consumption, Mount Vernon, Hampstead, has received a donation of £1000 to name a bed "in memory of the late Mrs. Henry Claudet, who died at Cannes."—The committee of the Cardiff Infirmary have received £1050 from an anonymous donor.

**AN ISOLATION HOSPITAL FOR KINGSWOOD.**—The medical officer of health (Mr. C. J. Perrott) of the urban district of Kingswood, near Bristol, is urging his council to provide an isolation hospital. There can be no doubt that one is needed, for the population of the district has increased during the last decade from 9000 to nearly 12,000 and during September there occurred 13 cases of typhoid fever, one of which terminated fatally.

**WATER-SUPPLY OF THE BRIDGWATER RURAL DISTRICT COUNCIL.**—Colonel A. Hepper, Local Government Board inspector, held an inquiry at Bridgwater on Oct. 10th into an application by the rural district council for sanction to borrow £24,000 for the purposes of carrying out a water-supply for six of the rural parishes. Evidence was given showing that the water used by the inhabitants from wells, and the like, was very impure and had led to outbreaks of infectious diseases.

**GUY'S HOSPITAL.**—Sir Joseph Dimsdale, M.P., Lord Mayor elect, has promised to preside at a Mansion House meeting to be held early in January next in furtherance of the appeal of this hospital for a renewal of public support. A sum of £180,000 is required to meet the cost of many works of renovation and extension rendered necessary by the age of the hospital and the constantly increasing demands upon its ministrations. The appeal also asks that the income of the hospital derived from voluntary sources may be increased to £25,000 per annum.

**ENTRANCE SCHOLARSHIPS.**—The following entrance scholarships have been awarded at St. Mary's Hospital Medical School:—Open Scholarship in Natural Science, value £145, W. L. Holyoak (Wyggeston Schools, Leicester); Open Scholarship in Natural Science, value £78 15s., F. C. H. Bennett; Open Scholarship in Natural Science, value £78 15s., L. Colebrook; Open Scholarship in Natural Science, value £52 10s., E. Balthasar. University Scholarships of £63 each, W. E. Paramore (St. John's College, Cambridge) and H. E. Kitchen (Sidney Sussex College, Cambridge). Epsom Scholarship (by nomination), A. J. May (Epsom College).

**ENTERIC FEVER AT PLYMOUTH.**—At a meeting of the sanitary committee of the Plymouth Borough Council held at the end of September the medical officer of health (Mr. F. M. Williams) reported that from the last few days of August up to the end of September 34 cases of enteric fever had been notified. The enteric fever wards of the Borough Hospital were over-full (22 cases in wards to accommodate 16) and applicants for admission had to be refused. The outbreak had been traced to drinking water from storage tanks, defective house-drains, and to the disturbance of a filthy subsoil for the reconstruction of new sewers.

**DUTIES OF DISTRICT MEDICAL OFFICERS.**—At the meeting of the visiting committee of the Newton Abbot Board of Guardians held on Oct. 9th one of the district medical officers who had been requested to mention the salary he would require for attendance upon children in the new cottage homes of the guardians, stated that he would undertake the duties for a period of one year at a fee of £5 per home. One of the guardians considered that the medical officer should perform the duties without any extra remuneration as the children resided in his district, but the clerk disagreed entirely with that view, and eventually the matter was referred to the medical committee.

Messrs. George Jennings, Limited, have received a notification of appointment of sanitary engineers to His Majesty the King.

## BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, 156, Charing-cross-road, W.C.

John Bull: His Origin and Character, and the Present Condition of His Big Property, and Two other Papers on Education. By Cecil Roddie. Price 6d.

ARNOLD, EDWARD, 37, Bedford-street, Strand, W.C.

Phototherapy. By Professor Niels R. Finzen, Copenhagen. Translated from the German edition, and with an Appendix on the Light Treatment of Lupus. By James H. Sequeira, M.D., Lond., M.R.C.P. Price 4s. 6d.

CHURCHILL, J. & A., 7, Great Marlborough-street, W.

A Simple Method of Water Analysis, especially designed for the use of Medical Officers of Health. By John C. Thresh, M.D. Vict., D.Sc. Lond., D.P.H. Cantab. Third edition. Price 2s. 6d.

An Introduction to the Bacteriological Examination of Water. By W. H. Horrocks, M.B., B.Sc. Lond. Price 10s. 6d.

Outlines of Gynaecology, Pathology, and Morbid Anatomy. By C. Hubert Roberts, M.D. Lond., F.R.C.S. Eng., M.R. J.P. Price 21s.

A Manual of Practical Anatomy. By the late Professor Alfred W. Hughes, M.B., M.C. Edin., &c. Edited and completed by Arthur Keith, M.D. Abern., F.R.C.S. Eng. In Three Parts. Part I., The Upper and Lower Extremities. Price 10s. 6d.

CONSTABLE, ARCHIBALD, AND CO., LIMITED, 2, Whitehall-gardens, S.W.

The Life of Pasteur. By René Vallery-Radot. Translated from the French by Mrs. R. L. Devonshire. Two volumes. Price not stated.

Lehrbuch der Physiologie des Menschen. By G. von Bunge, Professor in Basel. Vol. II. Price 15 marks.

WRIGHT, J. AND Co., Stonebridge, Bristol.

Illustrations from "First Aid to the Injured and Sick." By Dr. Warwick and Dr. Tunstall. Diagrams for the use of lecturers. Sets of 16 sheets, price 27s. 6d., or in single sheets.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BARBOUR, J. M., M.B. Glasg., has been appointed Resident Physician, Mendip Hills Sanatorium, Hill Grove, over Wells, Somerset.

BONNEY, W. F. VICTOR, M.D., M.S. Lond., F.R.C.S. Eng., M.R.C.P., has been appointed Physician Accoucheur to the St. Pancras and Northern Dispensary.

DAVIS, HARRY, M.R.C.S., L.R.C.P., L.S.A., D.P.H. Cantab., has been appointed Medical Officer of Health for Callington, Cornwall.

HODGSON, J. F., M.B., Ch.B. Vict., has been appointed Resident Medical Officer of the Halifax Union Poor-law Hospital.

MATHESON, RODERICK M., M.D., M.S. Edin., has been appointed Honorary Assistant Surgeon to Noble's Isle of Man Hospital.

PARSONS, JOHN HERBERT, M.B., B.S., B.Sc. Lond., F.R.C.S., has been appointed Curator and Librarian to the Royal London Ophthalmic Hospital.

PEGGE, EDWARD VERNON, L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health for Briton Ferry, Glamorgan-shire.

RODGERS, R. CRAIG, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Medical Officer to the Burnley Victoria Hospital, vice Dr. James Mackenzie, resigned.

WHITE, MAURICE FORBES, M.B., Ch.B. Aberd., has been appointed Resident Surgeon to the Birmingham General Dispensary.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BELGRAVE HOSPITAL FOR CHILDREN.—Honorary Dental Surgeon.  
BETHNAL GREEN INFIRMARY.—Assistant Medical Officer. Salary at rate of £100 per annum, with furnished apartments, board, and washing.

BIRMINGHAM CITY ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 a year, with board, apartments, and washing.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeon, unmarried, Salary £150 per annum, with rooms, fire, lights, and attendance.

BRADFORD ROYAL INFIRMARY.—House Surgeon, unmarried. Salary £110 per annum, with board and residence. Also Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

BRISTOL GENERAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board, residence, &c.

CHIKSEA, BROMPTON, AND BELGRAVE DISPENSARY, Sloane-square, Chelsea, S.W.—Honorary Surgeon.

CHIKSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Registrar. Honorarium 20 guineas per annum.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer, unmarried. Salary £120, rising to £150, with board, apartments, laundry, &c.

DERBY COUNTY ASYLUM, Mickleover.—Junior Assistant Medical Officer. Salary £110, rising to £130 per annum, with apartments, board, washing, and attendance.

DERBYSHIRE ROYAL INFIRMARY, Derby.—Assistant House Surgeon for six months. Salary £30 for the six months, with board, residence, and washing.

DUBLIN, TRINITY COLLEGE.—King's Professorship of the Institute of Medicine (Physiology and Histology) in the School of Physic.  
ESSEX COUNTY ASYLUM, Brentwood.—Junior Assistant Medical Officer. Salary £140 per annum.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeon for six months. Remuneration at rate of £30 per annum, with board, residence, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Medical Officer. Salary £200 per annum, with board and residence.

HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W.—Senior Clinical Assistants for six months, renewable.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £20, washing allowance £2 10s., with board and residence; also Surgeon Dentist.

HUDDERSFIELD INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and washing.

INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Junior House Surgeon. Salary £75 per annum, with residence, board, and washing.

LEICESTER INFIRMARY.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing.

LONDON COUNTY ASYLUM, Hanwell, W.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing.

LONDON DISPENSARY, 27, Fournier-street, Spitalfields, E.—Assistant Medical Officer. Salary £90 per annum.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £70 per annum, with board and residence.

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon.—Honorarium at rate of £50 per annum and board.

MORPETH DISPENSARY.—House Surgeon, unmarried. Salary £120 per annum, with rooms, coals, gas, and attendance.

NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Fitzroy-square, W.—Clinical Assistant for six months. Honorarium at rate of £35 per annum.

PLYMOUTH BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with apartments, board, and washing.

PRETORIA CIVIL HOSPITAL, Transvaal.—Resident Assistant Medical Officer for three years, unmarried. Salary £300, £350, and £400, with board, lodging, and washing. Allowance of £60 on arrival in Pretoria for travelling expenses.

ROTHERHAM HOSPITAL.—Assistant House Surgeon. Salary £80 per annum, with board, &c.

ROYAL CORNWALL INFIRMARY.—House Surgeon, unmarried. Salary £100, increasing by £10 a year, with board and apartments.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Ventnor.—Resident Medical Officer, unmarried. Salary £150 per annum, with board and lodging.

ROYAL SEA BATHING HOSPITAL, Margate.—Resident Surgeon, as Junior for six months and then as Senior for the like period. Salary at rate of £80 and £120 per annum respectively, with board and residence. Also Honorary Visiting Surgeon and Honorary Assistant Visiting Surgeon.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Surgeon and Assistant Surgeon.

ROYAL VICTORIA HOSPITAL, Belfast.—Medical Superintendent. Salary £300 per annum, with board and apartments.

SALISBURY INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with board, lodging, and washing.

TEIGNMOUTH HOSPITAL, SOUTH DEVON.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

WESTERN GENERAL DISPENSARY, Marylebone-road.—Honorary Physician.

YORK COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £110 a year, with board, lodging, and attendance.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory Acts at Buckingham; and at Ironbridge and Bridgnorth, Salop.

## Births, Marriages, and Deaths.

### BIRTHS.

COLLICTT.—On the 14th Oct., at 2, S. Peter's-place, Brighton, the wife of Arthur M. Collicutt, M.B., of a daughter.

FOULDS.—On Oct. 8th, at Ashlea, Droitwich, the wife of Francis H. Foulds, M.R.C.S., L.R.C.P. Lond., of a daughter.

PERSHOUSE.—On Oct. 13th, at Chipchase, Hadley Wood, the wife of Frank Pershouse, M.R.C.S., L.R.C.P. Lond., of a son.

RAY.—On the 11th inst., at 48, The Crescent, Salford, the wife of John Howson Ray, Ch.M., F.R.C.S., of a son.

SMITH.—On Sept. 8th, at Cawnpore, N.W.P. India, the wife of Captain Herbert Austen Smith, I.M.S., of twins, boy and girl.

SPRAGUE.—On Oct. 7th, at Saffron Walden, the wife of W. Carr Sprague, M.D. Edin., of a son.

STANFORD.—On Oct. 7th, at Sutton Valence, Maidstone, the wife of W. Bedell Stanford, M.R.C.S., L.R.C.P. Lond., of a daughter.

### MARRIAGES.

BROWN—PULLEN.—On Oct. 16th, at St. Helen's Church, Abingdon, Berks, by the Rev. H. T. Maitland, M.A., Thomas Henry Brown, M.A., M.B., B.C. Camb., of Hampton-in-Arden, Warwickshire, younger son of Thomas Brown, Hunstanton, Norfolk, to Isabel Mary, eldest daughter of Richard Pullen.

HANCOCK—LEUCHARS.—On the 15th October, 1901, at the parish church, Isleworth, by the Rev. J. H. Champion McGill, assisted by the Rev. C. A. Morgan, vicar of All Souls, St. Margaret's, Twickenham, George Charles Hancock, M.R.C.S., L.R.C.P., D.P.H. Lond., second son of Thomas Webster Hancock, of Treskelly, St. Margaret's, Twickenham, to Edie, only daughter of John Walter Leuchars, of The Chestnuts, St. Margaret's, Twickenham, and of Durban, Natal.

PRITCHARD—SILLS.—On Oct. 8th, at Barrowby Church, Grantham, Edward J. Pritchard, M.R.C.S., L.R.C.P. Lond., to Maud, youngest daughter of George Silles.

### DEATHS.

DICKINSON.—On Oct. 10th, at 2, Grove-park, Liverpool, in his 59th year, Edward Harriman Dickinson, M.D., F.R.C.P.

LIVINGSTONE.—On Oct. 4th, at 17, Hill-street, Wishaw, Lanarkshire, James Livingstone, M.D., L.R.C.S.E., J.P., aged 67 years.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

## Notes, Short Comments, and Answers to Correspondents.

### "HOW DISEASE IS SPREAD."

At Coventry, on Oct. 9th, a married woman was fined 2s. 6d. and costs for exposing her child suffering from scarlet fever. The town clerk said that there had been an extensive epidemic of scarlet fever in the city and remarked that it was useless for the authorities to spend money on isolation if patients were allowed to run about the streets. Quite so, but until the law deals more severely with people who for their own individual convenience endanger the community at large we fear there will be little, if any, improvement in this state of things. Only last week we commented on the case of a man who travelled from Leeds to Southampton knowing himself to be suffering from scarlet fever. In this case he was fined 40s. and costs, but if the maximum penalty of £5 were more often inflicted we should probably hear of these cases less frequently. Yet another case is reported from Marton, Lancashire, in which a child suffering from scarlet fever was on two occasions exposed on the public highway though the guardian of the child had been warned by the sanitary inspector that the patient must not leave the house until the rooms had been disinfected. In this case the magistrate remarked that in his opinion several of the additional cases reported (the medical officer in his evidence had stated that there had been one other case previous to the present one and there had been 28 cases since) had been brought about in consequence of the child in question being exposed. The fine was 10s. and costs in each case.

### THE TREATMENT OF ASTHMA.

To the Editors of THE LANCET.

SIRS,—I should be very much obliged if you or any of your readers would advise me on the following case in the next issue of THE LANCET. A boy, aged 15 years, has suffered for five years from asthma with bronchial troubles. He is a strong boy except when the asthma attacks come on and has been brought up on a farm. His parents' residence is on a very bleak spot, almost surrounded by the sea and swept by every wind, especially the east. His parents have no relatives in any inland or sheltered place and are not in very good circumstances. The boy's education has not been carried out very well. Could you advise me in any way what to do for him? Is there any institution, farm, or any place in the three kingdoms where he would be received and get some education? His parents could only afford a very small outlay. They are of the better-class farmers but not well off. If the boy could get to some sheltered inland place he would most probably get over his attacks altogether.

I am, Sirs, yours faithfully,

Oct. 10th, 1901.

M. B. T.

### "HIGH FREQUENCY CURRENTS AND DIABETES."

To the Editors of THE LANCET.

SIRS,—In answer to S. L. B. W. (THE LANCET, Oct. 5th, p. 954) who desires information on the influence and application of Tesla's currents in diabetes, I am pleased to say that in many cases great good can be effected and the elimination of sugar reduced to a minimum. Failure by this means has been experienced, not infrequently, but attention to the following details will reduce the percentage of failures: (1) the cause of the glycosuria (as this should be reckoned as a symptom and not as a disease), and (2) the position of the electrode. 1. The cause may be (a) cerebro-spinal, from either tumours, extravasations, or simply hyperæmia in the region of the floor of the fourth ventricle itself or in the cervical or upper dorsal regions of the spinal cord, or (b) pancreatic, from disease of that organ. 2. The position of the electrode in (a) should be close to the occiput. The electrode should be small and the current at first sent through the resonator from the first or second coil of the solenoid, then through the third at the second séance, and so on until full power is reached. Ten minutes daily is quite long enough. In (b) the electrode should be large and placed over the region of the head of the pancreas, with full power of current from the commencement. A séance should last 15 minutes. The interval between the applications and the duration of the series will be best determined in each individual case by the temperature of the patient.

I am, Sirs, yours faithfully,

HORACE MANDERS, M.D. Brux., F.R.C.S. Eng.

Bentinck-street, W., Oct. 14th, 1901.

### MEDICAL BOOKKEEPING.

MR. EDMUND SAYWELL, chartered accountant, of 6, Wheeler-gate, Nottingham, has submitted to us specimen rulings of books which he has specially prepared for the keeping of the accounts of the general practitioner. The day-book and attendance record are ruled to exhibit on one opening the attendances on a patient for a complete month, and any sums which may be paid by the patient, the totals of debits and credits at the end of the month being carried forward to the ledger, which latter is ruled for quarterly accounts and takes in 12 months at an opening. The private cash-book is designed to show the

whole of the financial transactions of the practitioner, and from it he can ascertain at any time the exact state of his bank balance. As the result of our imaginary experience in visiting patients, giving the usual attention to their ailments, and receiving certain amounts from them on account of professional services; paying for drugs, instruments, horses, servants' wages, butchers' and grocers' bills, and rent and taxes; and crediting ourselves with our (still imaginary) receipts from investments, rents of property, &c., and also from patients' fees, and entering all these details up in the rulings provided by Mr. Saywell, we feel able to say that his scheme of medical bookkeeping is simple, convenient, and well suited to the requirements of the busy practitioner.

### "A NEW 'CONSCIENTIOUS OBJECTION.'"

To the Editors of THE LANCET.

SIRS,—The great value of hæmoglobin preparations in certain morbid conditions being now well-established, it interested me to find a patient suffering from neurasthenia with anæmia professing a conscientious objection to taking one of the best known of these preparations on the ground of its being "blood," and therefore expressly forbidden in Holy Writ both to Jew and Christian. In their advertisement of this preparation it is set forth by the manufacturers that it consists in effect of dehydrated blood rendered palatable by the addition of glycerine and a little wine. This is certainly an improvement on what was, I believe, the original method of administering hæmoglobin (depicted with horrid realism in a picture entitled "Les Buveurs de Sang" in the Salon of 1898)—viz., the conducting of patients to the abattoirs, where the blood was handed to them in tumblers fresh from the severed vessels. One can understand objections apart from any question of creed being made to this method of taking a remedy. As, however, religious scruples and sickness are frequently of intimate association (men have died for conscience' sake before now), it is possible for this conscientious objection to a therapeutic agent likely to be much used in the near future to become widespread. The passages of Scripture on which it is founded are as follows. St. James, speaking in Acts xv. 19, 20, 21, says:—

"Wherefore my sentence is, that we trouble not them, which from among the Gentiles are turned to God;

But that we write unto them, that they abstain from pollutions of idols, and from fornication, and from things strangled, and from blood.

For Moses of old time hath in every city them that preach him, being read in the synagogues every sabbath day."

And again in verses 28 and 29:—

"For it seemed good to the Holy Ghost, and to us, to lay upon you no greater burden than these necessary things;

That ye abstain from meats offered to idols, and from blood, and from things strangled, and from fornication," &c.

Also in Acts xxi. 25, the elders of the believing Jews addressing St. Paul say:—

"As touching the Gentiles which believe, we have written and concluded that they observe no such thing, save only that they keep themselves from things offered to idols, and from blood, and from strangled, and from fornication."

These passages, as far as drinking blood is concerned, have reference to the charge in the Mosaic code to be found in Leviticus xvii. 10-14, the last verse of which runs as follows:—

"For it is the life of all flesh; the blood of it is for the life thereof: therefore I said unto the children of Israel, ye shall eat the blood of no manner of flesh: for the life of all flesh is the blood thereof: whosoever eateth it shall be cut off."

And again in Deuteronomy xii. 23-24:—

"Only be sure that thou eat not the blood: for the blood is the life; and thou mayest not eat the life with the flesh.

Thou shalt not eat it; thou shalt pour it upon the earth as water."

The drinking of blood was also forbidden to Noah and his descendants in Gen. ix. 4. According to the Revised Version "life" may also be translated as "soul." Fraser, in his monumental work "The Golden Bough," points out that this belief that the life or soul of the animal was identical with the blood was not confined to the Jews. It was or is shared by widely divergent races as represented by the Esthonians, the Romans, the Arabs, some of the Papuan tribes and the North American Indians, who in consequence feared to drink it lest the soul of the animal should enter their bodies. On the other hand, it is interesting to note that in one more therapeutic measure we have been anticipated by the Chinese. In a work entitled "Social Life of the Chinese," by the Rev. Justus Doolittle, an American missionary, published in 1865, we read, p. 390:—

"The Chinese here (Fuhchau) are in the habit of using as food the blood of several domestic animals, as fowls, swine, and goats. .... Some sick people or those who are troubled with want of appetite are fond of the blood of the goat boiled with vinegar and onions or garlic. It is said that thus prepared the blood gives them a relish for their food."

As to modern Christians feeling scruples about taking blood, it seems to me (without, however, any wish to enter the arena of religious

controversy) that the reference to the synagogues in Acts xv. 21 (quoted above) supplies the reason for the injunction to the early Christians—they were not to scandalise the devout Jews by doing things repugnant to the Jewish code of morals and thereby causing prejudice against the New Religion. Fornication is, of course, forbidden elsewhere in the New Testament, but the objections to the other items have surely lost their *raison d'être* at the present day; else roast chicken would also be taboo, and the only butcher for the Christian would be the kosher. As other medical men may meet with this objection and be nonplussed unless forewarned, I beg to offer the above suggestions for overcoming scruples. It is, I believe, mostly confined to that section of the religious community known as Plymouth Brethren, but it may become more widely diffused. There is no complaint so catching as a "conscientious objection."—I am, Sirs, yours faithfully,

J. S. MACINTOSH, M.R.C.S. Eng., L.R.C.P. Lond.

Platt's-lane, Hampstead, Oct. 14th, 1901.

#### A PLANT-BEARING MAMMAL.

In the October number of *Knowledge* Mr. R. Lyddeker gives an interesting account of the striking peculiarity which is to be observed in the outer hair of the sloths inhabiting the tropical forests of South and Central America. The outer hair of these animals is more or less green in colour—a very rare tint among mammals—the object of this colourisation being apparently to assimilate the animal to its leafy surroundings. It has long been known that this peculiar green tint is due to the presence of algae, but the subject has recently been reinvestigated by Dr. W. G. Ridewood, and it is these investigations which have suggested Mr. Lyddeker's article. The algae grow in transverse cracks of the outer sheath of the hair in the *ai*, but in the two-toed sloth the hair which lacks the outer sheath of the *ai* is furrowed with longitudinal grooves in which the algae flourishes. The species of the algae is also quite distinct in the two cases. After briefly discussing the question of "mimicry" Mr. Lyddeker deals with the manner in which the growth of algae is maintained from one generation of sloths to another. "The only rational explanation which presents itself is that the young sloths become infected with alga-spores from their parents. .... Dr. Ridewood has pointed out that in very young individuals of the two-toed sloth a large proportion of the hairs are devoid of grooves, and it would therefore seem that the young sloths do not develop a growth of alga till about the time they are old enough to leave the maternal arms and hang independently on the leafy and lichen-clad boughs of their native forests."

#### THE PREPARATION OF WAX MODELS.

In a paper read before the Philadelphia College of Physicians by Dr. J. F. Schomberg and published in the University of Pennsylvania *Medical Bulletin* appears some useful information on the making of wax models for clinical teaching and other purposes. The plaster of Paris used by dentists is recommended for the casts and is prepared for use by sprinkling it in handfuls or through a sieve into a basin of water until the water will absorb no more plaster. After the plaster is submerged the mass is stirred until it acquires a creamy consistence, when it is poured upon the skin. Previously, however, the surface of the part to be modelled is rubbed with olive oil or where hair is present with a stiff ointment such as resin cerate. The eyelashes should be well greased with vaseline. The following is the wax composition employed: white wax, one part; yellow wax, two parts; paraffin (about 54° C. melting-point), one part; starch, two parts; talcum, three parts. The wax and paraffin are melted together upon a water-bath in an ordinary double boiler, and the starch and talcum, previously mixed, are thoroughly stirred into the mass. "Either a small quantity of powdered carmine may be rubbed up with the starch and talcum, or it may be dissolved in alcohol and the necessary quantity poured in and stirred. The wax is now poured into the mould up to the brim and then poured back again into the receptacle. It is important in this first pouring to bring the wax rapidly into contact with the entire surface of the mould, otherwise indelible furrows will be produced in the resulting models. The pourings are now repeated until the model has acquired a sufficient thickness (ordinarily from one-quarter to three-eighths of an inch). It is then allowed to cool, after which the plaster cast is broken piece-meal from the model. Where there are no undercuts the model may often be removed from the cast without destroying the latter. To accomplish this the model must be removed before it is quite hard, while it still has some elasticity."

#### "SUPERFLUITY OF CATS."

THE *Evening News* of Tuesday, Oct. 8th, has the following:—

"One of the strangest applications ever made was considered by the Works Committee of the St. Pancras Borough Council at its last meeting. A lady tendered for cremation in the public destructor sixty or eighty unwanted cats per diem, for which she was prepared to pay 1d. a head. As, however, it was stated that the home she conducts charges 1s. per cat, it was recommended that the application should not be entertained. Ultimately the matter was adjourned for further information from the Health Committee."

Persons who advertise for lost cats, we believe, usually receive from an anti-vivisection society circulars which by inference suggest that

the advertiser's cat would probably be found in one of our scientific research laboratories. Such suggestions are hardly worthy of notice by intelligent people, and from the above paragraph it would seem that more cats than are required for purposes of science are to be found without robbing other people of their pets.

#### HOMES FOR EPILEPSY.

To the Editors of THE LANCET.

SIRS,—Would any of your readers tell me of an institution where a young man subject to epileptic fits could be taken by paying a small sum per week? I should esteem it a great favour if anyone could inform me.

Oct. 17th, 1901.

I am, Sirs, yours faithfully,

M.D.

#### STEPNEY OLD CHURCH.

ART and antiquity have suffered irreparable loss in the destruction by fire of the chancel of Stepney Church, a building dating from 1485. The glass and the carved work of roof and stalls can, of course, never be really replaced. The church is celebrated for its monuments which are remarkable either for commemorating famous men or for the curiousness of the inscriptions upon them, of which the following is an example. The simplicity and dignity of the language, as well as the commemoration of the fate which overtook the hapless family, may be commended at the present juncture to the anti-vaccination fanatics.

"Here Thomas Saffin lies interred—Ah why?

Born in New England, died in London die.

Was the third son of eight begot upon

His mother Martha by his father John.

Much favoured by his prince he 'gan to be,

But nipt by death at th' age of twenty-three,

Fatal to him was that we small-pox name,

By which his mother and two brethren came

Also to breathe their last nine years before,

And now have left their father to deplore

The loss of all his children with his wife,

Who was the joy and comfort of his life.

Deceased June 18th, 1687."

#### QUERIES ABOUT NEW ZEALAND.

A CORRESPONDENT wishes to know whether any of our readers can give him information on the following points: (1) the name of the best New Zealand medical journal; (2) up-to-date works descriptive of the country; (3) is it a good healthy country to live in and is there plenty of sunshine?

*H<sub>2</sub>BO<sub>3</sub>*.—The subject which our correspondent refers to has been dealt with again and again in our columns. Little more need be said until the report of the Departmental Committee appointed to investigate the use of preservatives in food is published and we learn that this report has already been laid upon the table of the House of Commons.

Mr. A. Lemarchant.—1. We fancy that there is no limit of time other than the statutory limit allowed for ordinary debts. 2. The ordinary notification slip is generally allowed as a claim, and we do not think that the local authority in question has any right to demand that another set of certificates should be forwarded.

Major.—We think that B was wrong to conduct such a canvass unknown to A.

D. M. K.—We think our correspondent must have a claim.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

#### METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

THE LANCET Office, Oct. 17th, 1901.

Date.	Barometer reduced to Sea Level and 32° F.	Direction of Wind.	Rain-fall.	Solar Radiation in Vacuum.	Maximum Temp. Shade.	Min. Temp.	Wet Bulb.	Dry Bulb.	Remarks at 8.30 a.m.

During the week marked copies of the following newspapers have been received:—*Sunday Times, Liverpool Daily Post, Yorkshire Post, Surrey Advertiser, Cardiff Mail, Morning Advertiser, Hertfordshire Mercury, Reading Mercury, Windsor and Eton Express, Mining Journal, Bristol Mercury, Leeds Mercury, Deutsche Medizinische Wochenschrift, Notts Express, Glasgow Herald, Sunderland Echo, Birmingham Gazette, Evening Standard, Standard, Bridgewater Mercury, Vanity Fair, The Globe, Science Signings, Scientific American, Literary Digest, Engineer, &c.*

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY (21st).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopaedic (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY (22nd).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Bar (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY (23rd).**—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY (24th).**—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY (25th).**—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**SATURDAY (26th).**—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**TUESDAY (22nd).**—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Dr. H. Campbell Thomson: Acute Dilatation of the Stomach, with illustrative cases.

**WEDNESDAY (23rd).**—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Meeting.

**HUNTERIAN SOCIETY** (London Institution, Finsbury-circus, E.C.).—8.30 P.M. Clinical Evening.

**FRIDAY (25th).**—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8 P.M. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 P.M. to 9 P.M.

**INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH** (Hotel Cecil, Strand, W.C.).—5 P.M. Annual General Meeting. Prof. A. Wynter Blyth: Ventilation, (Presidential Address). 7 P.M. Annual Dinner.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (21st).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. J. J. Pringle: Clinique. (Skin.)

**POST-GRADUATE COLLEGE** (Lecture Room, West London Hospital, Hammersmith-road, W.).—Mr. R. Lloyd: The Administration of Anesthetics in Nose, Throat, and Mouth Cases.

**TUESDAY (22nd).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. R. L. Bowles: Clinique. (Medical.)

**POST-GRADUATE COLLEGE** (Lecture Room, West London Hospital, Hammersmith-road, W.).—Mr. Baskin: Minor Surgery.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Queens-square, Bloomsbury).—3.30 P.M. Sir W. Gowers: Cases in Hospital.

**WEDNESDAY (23rd).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. J. Berry: Clinique. (Surgical.)

**POST-GRADUATE COLLEGE** (Lecture Room, West London Hospital, Hammersmith-road, W.).—Mr. Eccles: Surgical Anatomy.

**LONDON THROAT HOSPITAL** (204, Great Portland-street, W.).—5 P.M. Dr. Stoker: Chronic Glandular Diseases of Naso-Pharynx. (Post-Graduate Course.)

**THURSDAY (24th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical.)

**POST-GRADUATE COLLEGE** (Lecture Room, West London Hospital, Hammersmith-road, W.).—Dr. Ball: The Examination of the Throat and Nose.

**THE HOSPITAL FOR SICK CHILDREN** (Gt. Ormond-street, W.C.).—4 P.M. Dr. Colman: Clinical Demonstration.

**CHANCING-CROSS HOSPITAL.**—4 P.M. Dr. Eden: Gynaecological Cases. (Post-Graduate Course.)

**LONDON TEMPERANCE HOSPITAL** (Hampstead-road, N.W.).—2 P.M. Dr. S. Fenwick: Clinical Demonstration.

**FRIDAY (25th).**—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M. Dr. StClair Thomson: Clinique. (Throat.)  
**POST-GRADUATE COLLEGE** (Lecture Room, West London Hospital, Hammersmith-road, W.).—Dr. Saunders: Therapeutics.  
**LONDON TEMPERANCE HOSPITAL** (Hampstead-road, N.W.).—2 P.M. Dr. P. Parkinson: Clinical Demonstration.

## EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only. AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsgagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Office, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			TO THE COLONIES AND ABROAD.		
One Year	...	£1 12 6	One Year	...	£1 14 8
Six Months	...	0 16 3	Six Months	...	0 17 4
Three Months	...	0 8 2	Three Months	...	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Office, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

### Communications, Letters, &c., have been received from—

- A.**—Mr. F. P. Atkinson, Bexhill; Association for the Supply of Pure Vaccine Lymph, Lond., Secretary of; Miss A.; Dr. J. Albano, Guardia Peticara, Italy; Dr. G. N. Adams, Kenfig Hill; Mr. A. R. Anderson, Nottingham; Messrs. Arnold and Sons, Lond.; Mr. W. Armstrong, Buxton; Mr. R. F. Abbey, Lond.; Messrs. R. Anderson and Co., Lond.

# The Harveian Oration.

Delivered before the Royal College of Physicians of London on  
St. Luke's Day, Oct. 18th, 1901,

By NORMAN MOORE, M.D. CANTAB.,  
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO, AND LECTURER ON THE PRINCIPLES AND  
PRACTICE OF MEDICINE AT, ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, AND GENTLEMEN HONOURING US BY YOUR PRESENCE TO-DAY.—It has long been the custom in the several ancient colleges of our universities to commemorate the founder and the benefactors on some particular day. The members of the colleges are assembled, the history of the foundation is related with due solemnity, and the names of the benefactors are mentioned with honour and gratitude. Dr. William Harvey, the illustrious man by whose injunction we are assembled to-day, was familiar with this custom, for it was enjoined by the founder of his college at Cambridge, Dr. John Caius, a physician who not only possessed learning but venerated it and had considered those ceremonies and decorations which are as appropriate to learned societies as the fine paper, well-formed type, and beautiful bindings in which great scholars and great readers such as Aldus, and Grolier, and Thuanus, and our own Bentley delighted to see good literature clothed. It was Caius who gave us the silver rod which our President carries at every meeting of this College. He desired that we should be ruled with the mildness and clemency which a silver sceptre typifies, while the four serpents which ornament the sceptre are to remind the President that wisdom is to govern his conduct. Dr. Caius when in London lived within the enclosure of St. Bartholomew's Hospital, and the first College feast was held there in 1556, exactly a 100 years before the delivery of the first Harveian Oration. There Dr. Caius died in 1573, a benefactor of the study of medicine, in which he was the first Englishman to write an original description of a disease,<sup>1</sup> to learning in general by the foundation of his college at Cambridge, to the poor of London by a gift to St. Bartholomew's Hospital, and to this College in several ways. In his annals of Caius College a resolution is recorded under the date Oct. 6th, 1531, urging the duty of gratitude and of the remembrance and record of benefactors. Thus it was early in life, at Caius, that Harvey learned the value of such acts of public gratitude as that which, on his institution, we keep to-day. Sir George Paget, a former fellow of Caius and of this College, Regius Professor of Physic in the University of Cambridge, and an example thereof of all that a physician should be, has shown that it was probably the teaching of anatomy instituted in his college by Caius which led Harvey to those studies in which his fame is immortal. There, too, he was imbued with the spirit of good fellowship in learning which was then prevalent in the University and has ever since pervaded its atmosphere. Caius had fostered this spirit in the college he founded which, robed in the architectural garb of the Renaissance, appropriately comes into view of a visitor to Cambridge immediately after the foundation of King Henry VI., refulgent with the last glorious days of mediæval learning.

The poets who knew Cambridge have told in verse what every man worthy of a liberal education has felt. Milton of Christ's, disposed as he was to resist the natural effect of religious art, was nevertheless profoundly affected by great architecture and has left the world the better by the impression which he received as an undergraduate from the chapel of King's:—

"But let my due feet never fail  
To walk the studious cloisters pale,  
And love the high embow'd roof,  
With antic pillars massy proof,  
And storied windows richly dight,  
Casting a dim religious light."

Wordsworth of St. John's, trying to study the depths

<sup>1</sup> A Boke or Counsell against the disease commonly called the Sweate or Sweatyng Sicknesse: made by Jhon Caius doctour in Philosophie. 1552.  
No. 4078.

of his own mind, found himself deeply affected by his surroundings:

"I could not print  
Ground where the grass had yielded to the steps  
Of generations of illustrious men  
Unmoved, I could not always lightly pass  
Through the same gateways, sleep where they had slept,  
Wake where they waked, range that enclosure old,  
That garden of great intellects—undisturbed."

Cowley of Trinity, a lesser poet than these, seems by the power with which he expressed another of the feelings of university life almost to justify Clarendon's remark that in his time he had in poesy "made a flight beyond all men."

"Ye fields of Cambridge, our dear Cambridge, say,  
Have ye not seen us walking every day?  
Was there a tree about which did not know  
The love betwixt us two?"

The introduction into the family of great minds, the permanent association with a venerable collegiate home and its usages, the ties of friendship—by all these Harvey had been influenced during his residence at Cambridge from 1593 to 1598. When he migrated to this College in the midst of a busy world, *Fumum et opes strepitumque Romæ*, yet no less devoted to one of the highest branches of learning, he was kindly received. Two physicians deserve commemoration for their early kindness to him; one was Dr. Ralph Wilkinson of Trinity College, Cambridge, in relation to whom he occupied at St. Bartholomew's the position which, Mr. President, I now have the honour with infinite advantage and satisfaction to myself to occupy towards you. The other was Dr. Lancelot Browne of Pembroke College, Cambridge, who had been one of the proctors in 1573, the year in which Edmund Spenser of that college took his degree. Perhaps Browne was one of the learned wits of whom the poet was thinking when he celebrated the Cam in the *Fairie Queen*:—

"My mother Cambridge, whom as with a crown  
He doth adorne and is adorned of it,  
With many a gentle muse and many a learned wit."

It was Dr. Browne's daughter Elizabeth whom Harvey married in 1604. His life in our College was one of continued friendship and learned conversation. He was welcomed in his youth, applauded in his discoveries, venerated in his age. When his life ended in 1657 his body was accompanied beyond the walls of the City by the President and the whole College on its way to its last resting-place at Hempstead in Essex. Our College was of about one-tenth its present size when Harvey was admitted, but it was nevertheless a society in which a great variety of learning was to be found and where a man could spend his days with advantage. His entrance into it was gradual, for those were the days, as Clarendon says, "when men were seen some time before they were known and well known before they were preferred." Harvey's relations with this College began in the first year of King James. At a meeting on April 21st, 1603, the Fellows had discussed whether they should go out to meet the King at his entry into London and salute him "*solemni oratione*." At the next meeting on May 4th, 1603, "Mr. Harvie, doctor of medicine in the University of Padua, attended and presented himself for examination and when examined answered to all questions sufficiently well." Nevertheless he was put off to another time, "*cum convenientia ad Prazin*," that is, with informal leave to practise in the interval. He appeared again on April 2nd, 1604. "Dr. Harvie was examined for the second time for the degree of candidate and his answering approved." At his first examination he was the sole candidate and only the President, Dr. Richard Forster, and three Fellows were present, a small attendance perhaps due to the plague then prevalent. At the second examination John Craige (the King's physician, newly come with His Majesty from Scotland), Thomas Hearne (an Oxonian, who like Harvey had graduated at Padua), Thomas Lodge (the poet), and Thomas Rawlins of Clare Hall, Cambridge, were also examined, and all approved but Lodge. On May 11th, 1604, Harvey was examined and approved for a third time and had for his companions Rawlins, Hearne, Edward Elwin of Corpus Christi College, Cambridge (afterwards physician to the King's household), and three poets, Matthew Gwin, Thomas Lodge, and Raphael Thorius. Of these poets Gwin was afterwards admitted a Fellow of the College. In our society, where, for the most part, we think,

"Nobis non licet esse tam disertis,  
Qui Musas collimus severiores."

it is remarkable that literature has never been neglected. In the translation of Plutarch's Lives, edited by Dryden,

10 Fellows of this College,<sup>2</sup> three of whom afterwards filled the office of President, took part; and to a greater biographical work of the present day, the greatest indeed which has appeared in our literature, you, Sir, have made a contribution, as well as our learned librarian, Dr. Payne, and some other Fellows of the College.

At the present day we have in Robert Bridges a master of verse which is both praised and read. Arbutnot, steeped in literature, gave a poetic form to thoughts which must constantly occupy the minds of physicians:

"Am I but what I seem, mere flesh and blood,  
A branching channel with a mazy flood?  
The purple stream that through my vessels glides  
Dull and unconscious flows like common juices,  
The pipes through which the circling juices stray?  
Are not that thinking I, no more than they?  
This frame, compacted with transcendent skill  
Of moving joints obedient to my will,  
Nursed from the fruitful glebe like yonder tree,  
Waxes and wastes: I call it mine not me."

Sir Samuel Garth was a popular poet for 50 years and to this day one couplet in his "Dispensary"—

"To die is landing on some distant shore  
Where tempests never beat nor billows roar"—

is known to everyone because it was admired by Cowper and is quoted by him in one of the most affecting poems in our language.<sup>3</sup> Harvey himself is one of the heroes of "The Dispensary":

"They hasten now to that delightful Plain  
Where the glad Manes of the Bless'd remain:  
Where Harvey gathers simples, to bestow  
Immortal youth on Heroes' shades below.  
Soon as the bright Hygeia was in view,  
The Venerable sage her Presence knew.  
Thus he:  
'Hail, blooming Goddess, thou propitious power,  
Whose blessings mortals more than life implore.  
With so much lustre your bright looks endear,  
That cottages are courts where those appear.  
Mankind as you vouchsafe to smile or frown  
Finds ease in chains, or anguish in a crown.'"<sup>4</sup>

The poets who began the march to fame with Harvey and whose poetic fancies were afterwards so far surpassed in repute by his precise facts deserve to be mentioned if only because they were associated with him on an important day of his life.

Matthew Gwin was the first professor of physic at Gresham College where he lectured from 1598 to 1607. He was an accomplished Latinist and took part in a medical disputation at Oxford for the entertainment of King James I. and his Queen Anne. He had to argue on the question whether the morals of nurses were imbibed by infants with the milk. It was a delicate point, for the King had had a drunken nurse and was always anxious that he should not be thought to have imbibed her evil nature. The King drank a good deal, yet his most steadfast brain, says Sir Theodore Mayerne,<sup>5</sup> was never disturbed by sea or by wine. Gwin published a Latin comedy, called *Vertumnus*, which was acted at Magdalen College, Oxford, and a Latin tragedy, *Nero*, based upon Tacitus, Suetonius, Dion Cassius, and Seneca. The epilogue of the comedy, where three sibyls hail King James by the several titles of his increasing dominions, is sometimes thought to have suggested to Shakespeare the famous salutations of the witches in *Macbeth*. The tragedy displays the reading of its author, but perhaps Dr. Gwin's last lines about Nero the Emperor may be applied to *Nero* the tragedy:

"Restatque de Nerone tam magno nihil  
Nisi quod sepulchrum condant aut ignis cremet."

Gwin had disputed before King James with Sir William Paddy, a benefactor here and at St. John's College, Oxford, as to whether smoking tobacco was conducive to health. Raphael Thorius, the Licentiate who attended to be examined with Gwin and Harvey, treated the same subject in a poem of two books, and in spite of the Royal opinion against

tobacco did not veil his own love for the fragrant weed, and he begins his "Hymnus Tabaci":

"Innocuos calices et amicum vatibus herbam  
Vimque datum folio, et lati miracula fumi  
Aggredior"—

and goes on to dedicate it to Sir William Paddy than whom, says Thorius, no one knew better the varied powers of the disease-repelling plant. Thorius wrote many lesser poems now chiefly interesting as showing his tastes and friendships. Three which have never been printed are addressed to L'Obel, the botanist, who was in practice in England as an apothecary, but who is known to few of the many who have the lobelia growing in their gardens. In 1625 Thorius sent his wife and family out of London to preserve them from the plague and, diligently attending to his patients, became infected and died.

Thomas Lodge, the third of the poets examined on the same day as Harvey, was a schoolfellow of Sir William Paddy, our President of 1609. He began life as a poet and ended it in the practice of medicine after a varied career, part of which was spent, as he says, "as a soldier and a scholler," and another part as a sea rover, hardly to be distinguished from a pirate. His story of "Rosalynde," written at sea "rough as hatcht in the stormes of the ocean and feathered in the surges of many perillous seas,"<sup>6</sup> and published in 1590, will always be memorable in literature for some fine lyric verses and still more as the source of the plot of Shakespeare's *As You Like It*. Lodge was often unfortunate in letters and in adventure and was so in his entrance to this College, for he did not receive a licence till 1609. He more often expresses gloom than cheerfulness in his verses and the feelings exhibited in a stanza of his "Margarite of America," written amid "bitter and extreme frosts at midsummer" in the Straits of Magellan, seem to have been often his:—

"From height of throne to abject wretchednesse,  
From wondrous skill to servile ignorance,  
From court to cart, from rich to rechelesnesse;  
The joys of life have no continuance.  
The King, the cattife wretch, the lay, the learned,  
Their crowns, woes, wants, and wits with griefe have earned."

On August 7th, 1604, at the house of Dr. Forster the President, Harvey and Elwin were again examined and Lodge was rejected. On Oct. 5th, 1604, the two former were sworn as candidates.

Of those who had been examined with him and approved Harvey was the last to be elected a Fellow. At that period the influence of great persons was sometimes brought to bear upon the College in the election of Fellows: Dr. Rawlins had a letter from the Archbishop of Canterbury; Dr. Gwin was recommended by Ellesmere, the Lord Chancellor, and by Thomas, Earl of Dorset, Lord Treasurer and Chancellor of the University of Oxford; and Dr. Elwin by the Earl of Suffolk, the Earl of Northampton, and the Earl of Salisbury, and by Lord Stanhope, and they were elected Fellows on Dec. 22nd, 1605, and Harvey not till May 16th, 1607. It is just to state that they were all older men. He took the oath and was admitted on June 5th, 1607, with two others, Dr. Matthew Lister, an Oxonian, and Dr. William Clement of Trinity Hall. Lister was afterwards knighted and became physician to the Queen of James I. and to King Charles I. as well as to Mary, Countess of Pembroke, in whose house he spent much time. He must often have talked to Ben Jonson, another frequenter of her house, and was, perhaps, one of the first to read and admire the epitaph written for the stately tomb which she deserved but which was never erected in Salisbury Cathedral, her place of burial:—

"Underneath this sable hearse  
Lies the subject of all verse—  
Sidney's sister, Pembroke's mother.  
Death! ere thou hast slain another  
Learn'd and fair and good as she,  
Time shall throw a dart at thee."

Clement, who like Harvey was a doctor of Padua, afterwards became Registrar of our College. Both he and Lister were industrious physicians, but all that has survived of their writings are four Latin verses by Lister and two by Clement, all in honour of the only medical book of Ralph Winterton, Regius Professor of Physic at Cambridge—a work which has perhaps received more praise from the learned than any other book written by a professor of medicine in that University. It is an edition of the "Aphorisms" of Hippocrates with a translation into Greek

<sup>2</sup> Dr. John Bateman (President, 1716-18)—Aratus; Dr. Edward Browne (President, 1704-7)—Themistocles and Sertorius; Dr. Walter Charleton (President, 1689-91)—Marcellus; Dr. William Crowne—Pyrrhus; Dr. Phineas Fowke—Phocion; Dr. Charles Frazer—Marcus Antonius; Dr. Thomas Fuller—Cicero; Sir Samuel Garth—Otho; Dr. Walter Needham—Agessilaus; and Dr. Thomas Short—Philopemen.

Cowper—"On the Receipt of my Mother's Picture out of Norfolk":

"So thou with sails how swift hast reached the shore  
'Where tempests never beat nor billows roar.'"

<sup>4</sup> The Dispensary: Canto vi., l., p. 298.  
<sup>5</sup> MS., Sloane, 1679 (British Museum), fol. 42.

<sup>6</sup> Rosalynde, Euphues golden legacie, London, 1590, p. 4 (reprint).

verse by Winterton, with also a Latin prose version and a translation into Latin verse. It was lauded in Latin or Greek verse by 17 Fellows of this College and two who subsequently became Fellows, one of whom was the celebrated Francis Glisson; by members of all the colleges at Cambridge but one and of several of the colleges of Oxford; while two university professors and the heads of Peterhouse, Queen's, Christ's, and Trinity commended it in Latin prose. What Johnson says of Pembroke College, Oxford, in his own time—"Sir, we are a nest of singing birds"—might have been declared of the College of Physicians in the reign of King Charles I.

Dr. Henry Atkins, the President, and afterwards a benefactor, of the College, was in the chair at the College meeting at which Harvey with Lister and Clement were admitted to the Fellowship. He was physician to James I. and is said to have been the first person to whom in 1611 that monarch offered the new rank of baronet. The first edition of our Pharmacopœia was published in 1618 under his auspices. Fourteen other Fellows were present, 10 of Harvey's University and four Oxonians,<sup>7</sup> while three of the 14 were doctors of Padua.<sup>8</sup> The business transacted after the new Fellows took their seats at the table is recorded in the "Annals." Dr. Mark Ridley was elected a censor in the room of Dr. William Dun, deceased. It was resolved that Dr. Edward Elwin should entertain the Fellows at a feast on the first Tuesday in the following July. Dr. Lister was to make preparations for the demonstrations in anatomy. Everyone was to try to learn where a certain Dr. Bonham had practised. Dr. Thomas Davis was elected Lumleian lecturer in succession to Dr. William Dun. Harvey, it will be remembered, succeeded Davis in this lectureship in 1615.

It would be pleasant to trace Harvey's relations with these and with the Fellows of subsequent elections throughout his time,

"But at my back I always hear  
Time's wingèd chariot hurrying near."<sup>9</sup>

One of those present at his admission was Dr. John Argent of Peterhouse who became *amicus suus singularis* and to whom with the College, of which Argent was then President, he dedicated in 1628 his "*Exercitatio Anatomica de Motu Cordis et Sanguinis in Animalibus*." The dedication shows how happy was his association with his contemporaries:

Since my book alone doth assert the blood to move and circulate by a new route quite different from that held, taught and explained through so many ages by countless and most illustrious and learned men I feared that I might be thought presumptuous if I should allow my little book which had been completed some years back to be published or sent over sea unless first I had stated it to you and had confirmed it by anatomical demonstration and had made answer to your doubts and objections and had received the judicial commendation of our illustrious President.

How plain are the friendly relations between Harvey and the other Fellows. Argent was his senior, as were those friends whom I have before mentioned, Wilkinson and Launcelot Browne, but he had also warm attachments among his juniors and none greater than those which bound him to George Ent and to Charles Scarborough. Ent was not three years old when Harvey was admitted a Fellow. They probably met for the first time in Rome in 1636. Ent had gone thither after five years' study at Padua which had succeeded his graduation at Sidney-Sussex College, Cambridge. They were both guests at dinner at the English College in Rome on Oct. 5th, 1636. Lovers of truth and members of the same university caring for the same branches of learning easily become friends, however different their ages, and the natural admiration which youth feels for old experience cements the friendship of generous minds. Of this there are fewer pictures more happy than Ent's account of Harvey in the dedication of the "*De Generatione Animalium*" to the President and Fellows of the College of Physicians in 1651. His preservation of this interesting treatise which might have been lost with other manuscripts of Harvey but for him, puts us under a debt of gratitude to Ent, who was President from 1670 to 1675 and Censor for 22 years, and he was also one of our pecuniary benefactors. Charles II. attended one of his anatomy

lectures and knighted him afterwards in the College. Thus it is in every way appropriate that his arms, sable between three hawk-bells a chevron or, should form part of the ornament of the Censor's room, to which they were brought from the old College in Warwick-lane.

Charles Scarborough, knighted by Charles II. in 1669, was younger than Ent. He obtained a Fellowship at Caius College and, ejected from his Fellowship as a Royalist, entered at Merton College, Oxford, when Harvey was Warden, and ever after enjoyed his friendship. Thus what seemed a misfortune, as is so often the case, proved his greatest advantage, and he might have said more truly than Dryden—

"Oxford to him a dearer name shall be  
Than his own mother university."

But this is no reason why a recent learned writer in his "*History of the Study of Mathematics at Cambridge*" should speak of him as "a teacher of the mathematics at Cambridge of whom I know nothing more." He was learned in mathematics; he had a fine mathematical library; and he translated Euclid. He was one of the famous men of his day and everyone who has read Johnson's "*Lives of the Poets*" will remember how Waller when he found his legs grow tumid "went to Windsor where Sir Charles Scarborough then attended the King, and requested him, as both a friend and a physician, to tell him what that swelling meant. 'Sir,' answered Scarborough, 'your blood will run no longer.' Waller repeated some lines of Virgil and went home to die." Scarborough was physician to three kings in succession, but will always be best remembered as the friend of Harvey and his successor at Harvey's request in the Lumleian lectureship. Harvey left Ent £5 to buy a memorial ring, and of Scarborough in his will says: "I give my velvet gown to my loving friend Dr. Scarborough and to Dr. Scarborough all my little silver instruments of surgery."

These examples show Harvey's feelings towards the men with whom he spent his life. He had known something of what is called "the great world." King Charles I. seems to have liked Harvey, who probably saw him in his best aspect and in intellectual relations which brought out his mental abilities and did not lead to the exhibition of those defects of character and of manner which, more than the turbulence of his subjects or the ambition of their leader, brought him to his tragic end. All Harvey's writings show him to have been simple and truthful, so that we may believe that what he had seen of the King had bred in him the admiration expressed in the dedication of his great book, where he compares the heart of animals, the sun of their microcosm, to the King in the State, the sun of his microcosm.

Harvey went to Italy in 1636 with Thomas Howard, Earl of Arundel. That nobleman's figure and manner are known to subsequent generations by his portrait in armour by Rubens and his description in Clarendon's History: "It cannot be denied," says the statesman, "that he had in his person, in his aspect and countenance the appearance of a great man which he preserved in his gait and motion. He wore and affected a habit very different from that of the time such as men had only beheld in the pictures of the most considerable men, all which drew the eyes of most and the reverence of many towards him as the image and representative of the primitive nobility and native gravity of the nobles when they had been most venerable." Even if he knew only a little about the vast collection of marbles, paintings, and manuscripts which he made abroad his table must have been one at which the conversation was worth attention. But it was in his own profession and in this College that Harvey found his most congenial society. Here were his happiest associations and the endowment of the oration was a sort of memorial of his life in the College.

How many men have generously tried, without vanity and in pure goodness of heart, to preserve for future generations some reminiscence precious to them of something in their own lives. What more striking example of this motive of benefaction could there be than the history of two Fellows of our College—Sir John Finch and Sir Thomas Baines. Finch, son of Sir Heneage Finch, Speaker of the House of Commons, graduated at Oxford in 1647. Two years later he went to reside in Christ's College, Cambridge, where he was introduced by Henry More, the Platonist, then tutor, to Thomas Baines of that college. They became friends at once and, the times making life in England uncomfortable for loyal men, both went to Padua, and there graduated M.D. On the King's restoration they came to England, and on Feb. 26th, 1661, were both elected Fellows of this College, a circumstance which it is proper to mention to-day, since our "*Annals*"

<sup>7</sup> Oxonians: Dr. Henry Atkins. Dr. Richard Foster (All Souls), Dr. Edward Jorjan, Dr. Thomas Hearne (Brasenose), and Dr. Matthew Gwin (St. John's). <sup>8</sup> Friar, Jorjan, and Hearne.

<sup>9</sup> Andrew Marvel.

declare that the election, which was not to be drawn into a precedent, was on account of all the benefits conferred on the College by the illustrious Dr. Harvey, "*nobis nunquam sine honore nominandi*," and by his brother Eliab. Finch's brother, the first Earl of Nottingham, a prominent and incorruptible statesman of Charles II.'s reign, had married Harvey's niece Elizabeth, the daughter of his brother Daniel, and it is a pleasant example of the honour in which Harvey was held after his death that this connexion was the ground of the election. I have seen a letter which shows that Harvey was respectfully remembered at Burley-on-the-Hill. It was written in 1719 and is dated "December 28th, the day on which poor Queen Mary died," and is from his wife to Daniel, second Earl of Nottingham. She is anxious about his health and advises him to copy from "your father's receipt book where among some directions of Dr. Harvey's I think there's one how the bone of a stag's heart is to be taken." Her ladyship adds that it may be unnecessary to take so serious a remedy but that none the less it will be well for her lord to have it by him. Finch cared for no honour which could not be equally conferred upon Baines, and when the King knighted him for services to the royal cause performed in Tuscany his request that his friend might be knighted too was granted. In almost every letter home Finch mentions Baines and, what is not always the case in such friendships, the family of Sir John Finch seem to have shared his attachment, as well as his respect for Baines as a physician. "Most dear nephew," says the Ambassador, writing from Pera, August 21st, 1680, "Sir Thomas Baines will write about the indisposition of your daughter" and the nephew (Lord Nottingham) writes to a friend, "The loss of Sir Thomas Baines was very great to me for I am sure he loved me." They were soon after incorporated doctors of medicine at Cambridge at the same congregation. In 1665 Finch was sent as Minister to the Grand Duke of Tuscany and in 1672 he succeeded Sir Daniel Harvey, Harvey's nephew, as Ambassador to the Sultan. Baines went to each court as physician to the embassy, and it was known, as is told in the Life of Sir Dudley North, that if you wanted to obtain any privilege at the embassy you must convince both Finch the Ambassador and Baines, whom the merchants called "the Chevalier." Baines died in September, 1682, and Finch resigned his office and returned home with the body. "I need not tell you," says his nephew in a letter which I have seen, "how deplorable a condition my poor uncle was in to lose so good a friend after 36 years' acquaintance. A few months later he died, not so much from fever and pleurisy as from the loss of Sir Thomas Baines. They founded two fellowships and two scholarships in remembrance of their own life-long friendship and in the hope that other such friendships might in after times be formed. They were both of dark complexion and grave aspect, as may be seen in two singularly fine portraits by Carlo Dolci in the drawing-room of Burley-on-the-Hill. They are buried under one marble canopy in the chapel of Christ's:—

"Whom joined in fame in friendship try'd  
No chance could sever nor the grave divide." 10

It was a similar feeling arising from the recollection of past happiness which led Harvey, who had often sat at table with the Fellows of this College and had enjoyed their conversation and lectured here for nearly 40 years, to establish the ceremony in which we take part to-day to commemorate benefactors, to promote kindly feeling, and to remind physicians that it is one of their duties to wrest secrets from nature for the improvement of medicine and the consequent benefit of mankind.

The oration used, as he had desired, to be in Latin, then the language of learning, of diplomacy, and of the literature which every educated man made his own—the Latin not only of the classics but of Augustine and Jerome, of Justinian, of Anselm, of Erasmus, of Scaliger, and of Grotius. The sympathy of our College with the revival of classical learning naturally led our orators to use the Latin of the Augustan age, not that living language, as it might justly be called, of the Church and the Law, so often condemned by scholars but deserving of our respect as men when we consider how many great minds have thought in it and how closely it is often associated with the very highest aspirations of mankind. It was, of course, the custom of Fellows of this College to address the learned in

their works and to write in Latin. Few medical books of the highest order were written in English by the Fellows of our College before "The Morbid Anatomy of Some of the Most Important Parts of the Human Body" of Dr. Matthew Baillie, afterwards a generous benefactor, which appeared in 1793, and the last great book in Latin was the "*Commentarii de Morborum Historia et Curatione*" of Dr. William Heberden, which was published in 1802, 12 months after his death in his ninety-first year. Let no one be led by a veneration for Latin literature to regret that our own language has since 1864 been substituted for Latin at this celebration. When Harvey gave his first lectures English literature was already rich, for the works of Shakespeare were complete and Chaucer, Spenser, and Marlowe and Beaumont and in prose the Chronicles, and the English writings of More, Fisher, Latimer, and Hooker, some fine versions of classical authors, and the first collection of Bacon's Essays, and many other good books were easily to be obtained, yet men had hardly come to understand with Ben Jonson how far the literature of the ancients had been surpassed.

"I will not seek  
For names; but call forth thund'ring Eschylus,  
Euripides, and Sophocles to us,  
Paccuvius, Accius, him of Cordova dead,  
To live again, to hear thy buskin tread,  
And shake a stage: or when thy socks were on,  
Leave thee alone for the comparison  
Of all that insolent Greece or haughty Rome  
Sent forth, or since did from their ashes come.  
Triumph, my Britain, thou hast one to show  
To whom all scenes of Europe homage owe.  
He was not of an age, but for all time,  
And all the Muses still were in their prime,  
When like Apollo he came forth to warn  
Our ears, or like a Mercury to charm."<sup>11</sup>

Since Harvey's day our literature, great as it was even then, has received such excellent and varied additions that it must always live among the noblest literatures of the world. How far do the speeches of Burke, greatest of political philosophers, surpass those of Cicero and of Demosthenes in depth of thought and in grandeur of expression; with splendid sentences, yet owing their force not to ornament but to the perfection with which they make clear the lofty argument and profound consideration of the subject. The verses of Dryden and of Milton, of Cowper and of Byron have shown what force metre may give to English, while the prose of Clarendon and Dryden, of Swift and Addison, of Bentley, of Johnson, of Fielding, of Goldsmith, of Blackstone, of Macaulay, and of Newman exhibit the extraordinary variety of excellence possible in the language. Is not Herrick superior to Catullus? and what ancient comedy approaches *She Stoops to Conquer* in the happy combination of the comedy of words with the comedy of action? Will not the letters of Cowper and of Swift and of Gilbert White bear comparison with those of Cicero and of Pliny? What is there in Latin literature which can be compared with the novels of Fielding or of Thackeray? Who would prefer Petronius Arbiter, or even—considering the Latin of later times and to mention one of the few romances which Harvey is likely to have read—who would be well advised to take up the "*Argenis*" of Barclay when he had within reach the "*Vicar of Wakefield*," the "*Pickwick Papers*," or the happy delineations of English everyday life of Jane Austen? Great as must always continue our admiration for classical Latin, willingly as we must reverence its dignity, its precision, its grace, deeply as we must feel that we have no authors who are the equals of Virgil and of Horace and of Lucretius in their several kinds, let us never regret its disuse on this day since we have substituted for it the language of our own far greater literature.

Harvey, following the good old custom which he had observed at Cambridge in accordance with the injunctions of Caius, desired us to commemorate our benefactors by name. We are not a rich society, but we have had many benefactors. Some good men have given us land and money, others have given us books, some pictures or busts, while others, again—and these are perhaps the greatest benefactors of all—have added to our corporate glory by the fame of their discoveries or of their learning. All these are our benefactors. We are grateful for a charter to the Sovereign who then styled himself "Henry, King of England and France, and Lord of Ireland." He favoured us in his best days and when in the tenth year of his reign he established our

<sup>10</sup> Tickell: To the Right Honourable the Earl of Warwick on the Death of Mr. Addison, Dodsley's Poems, I., 29.

<sup>11</sup> Ben Jonson: To the Memory of my Beloved Master, William Shakespeare, and what he hath left us.

corporate existence he deserved the commendations of More, who says in a letter to Bishop Fisher, "He is so affable and courteous to all men that each one thinks himself his favourite." Some of those to whom gratitude is due I have already mentioned, and as I cannot pretend to so terse a style as Thomas Newton of Cheshire,<sup>12</sup> who praises 215 botanists in 54 lines of Latin verse, I cannot hope to mention all our benefactors as they deserve.

Thomas Linacre, our founder, has impressed upon succeeding generations of physicians in England his own high ideal of what a physician's character and learning should be. His house in Knightrider-street was the first home of our College. He seems to join the ancient and the modern world, for he could remember the printing of the first book in England and learned Greek from Demetrius Chalcondylas, a Greek of Byzantium who read Homer as we should read Chaucer, conscious that the poems were in our own tongue whatever differences there might be of vocabulary or of phrase. Our library contains the noble Milan edition of 1499 of the Greek Lexicon of Suidas which was prepared by Linacre's teacher. It has no title-page, like many of the early printed books, but begins with a dialogue in Greek between the bookseller and a learned man which ends with an inquiry as to the price. "*χρυσῶν τριῶν*"—three gold pieces—says Bibliopoles. "Take them and give me the book," replies Philomathes. It is easy to imagine with what pleasure our founder must have contemplated such a book. The type is perhaps a reproduction of the Greek hand of Demetrius. Well-formed it is and impressed upon fine paper, yet as the text extends line after line over the pages with no interval or break, except the *τέλος τοῦ στοιχείου* and *ἀρχὴ τοῦ στοιχείου* of each letter, it brings home to a modern reader how much more perfect is the apparatus of learning in our day. We are sometimes told that so much is known now that there is no longer time to read books through and that men cannot seek knowledge in more than one direction. A comparison of this Suidas with a modern lexicon would rather suggest that where the means of acquiring it have become so much easier there must be time to learn more than in the days of our founder.

Sir William Paddy, who was well known to Harvey, was a benefactor of St. John's College, Oxford, as well as of this College, where he was President in 1609, 1610, 1611, and 1618. He is addressed by Thorius in words equally applicable to our present president:—

"Tu qui censu decoratus Equestri  
Virtutem titulis, titulos virtutibus ornas."

He was physician to Laud. "Few excellent men," says Clarendon of the Archbishop, "have ever had fewer friends to their persons." but Paddy was one of the few and a very faithful one. He left his library to St. John's, a fine collection of the scientific books of his time. Chancing to visit that library I asked if there was a separate list of his books and whether they could be pointed out in the cases. Receiving a negative reply to both questions, I asked for Gilbert de Magnete, thinking that Paddy would be sure to have a copy of that great work, of which the author, one of our benefactors, was President here in 1600 when Paddy was Censor. A fine copy was produced and on the first leaf was written "Liber Gulielmi Paddy." This clue made it easy to find several others of his books, Turner's New Herbal of 1551, Gerard's Herbal of 1597, Rondeletius and Guido, Fallopius and Laurentius, and that rare work of our Fellow, Edward Wotton, "De Differentibus Animalium," dedicated to Edward VI. and published in 1552, one of the first printed books on zoology by an Englishman. These required seeking on the shelves, but one book which belonged to Paddy is well known to every visitor to the library for it is displayed in a table case. It is a Royal copy of the 1615 edition of the Book of Common Prayer and contains in Paddy's hand an account of the last hours of King James I. As our late librarian, Dr. Munk, to whose Roll the fame of the College in the world of letters owes a good deal and who wrote a paper on the death of the King, was unacquainted with Paddy's record, it is, perhaps, known to few Fellows of the College, and deserves to be read here as a memorial of our former President and benefactor.

"Being sent for to Thibautte but two daies before the death of my covraigne Lord and master King James, I held it my Christian dutie to prepare him telling him that ther was nothing left for me to doe (in the afternoon before his death the next daie at noone) butt to pray for his soule. Whereupon the archbishop and the Lord Keeper, Bishop of Lincolne demanded iff his majestie would be pleased that they shoulde praye with hym. Whereunto he cheerfullie accorded and

after short praler these sentences were by the byshop of Lincolne distinctlie pronounced unto hym who with his eyes the gates of his hart lifted up unto heaven att the end of every sentence gave to us all thereby, a godly assurance of those Graces and livelie faith whereunto he apprehended the Merit of our Lord and onlie Saviour Christ Jesus accordinglie as in his godlie life he had often publiclie professed."

"WILL PADDY."

The 41 sentences which Bishop Williams recited to the King are written down, ending with the last verse of the Te Deum:

"In te Domine speravi non confundar in æternum."

Sir William Paddy died in 1634. In that year another benefactor was President and continued so for seven years—Simeon Fox, educated at Eton and at King's College, Cambridge. He was present in the Great Hall at Padua on Thursday, April 25th, 1602, when Harvey took his degree, and he saw him receive the insignia and ornaments of the doctorate, when the books were given to him first shut and then open, a golden ring placed upon his finger, the doctoral cap put upon his head, and finally the kiss of peace given to him with the blessing of authority. The name of Simeon Fox and those of Anthony Fortescue, Richard Willeby, Matthew Lister, Peter Munsel, and Robert Darcey, Englishmen, are recorded with others in the finely decorated diploma as witnesses to the ceremony. The only extant work of Fox is a Latin poem of 29 lines addressed to Winterton. He lived in the house which formed part of the College in Amen Corner and is buried in St. Paul's Cathedral. The bust erected in his honour in the College was unfortunately calcined in the Great Fire of London.

It would be easy if we had but time to-day to find something interesting to tell of each one of our benefactors. I should like to commemorate Assuerus Regemoster, Glisson's fellow-worker, by taking the College to the famous private school in Goldsmith's Rents, off Red Cross-street, where he was educated by Thomas Farnaby, that industrious editor of Juvenal, and Seneca, and Martial Lucan, Ovid, Terence, and Virgil, who had sailed with Sir Francis Drake, and whose learning was respected by Ben Jonson.

How delightful to accompany Dr. Edward Browne, son of Sir Thomas Browne and our President in 1704, in his travels to Larissa, where he hoped to breathe the atmosphere in which Hippocrates had practised and to know a little more of the Father of Medicine by contemplating the features of the country in which he had verified or established those aphorisms of medicine, the first of which is to this day placed before each individual Fellow at every meeting of our College. We might hear Alexander Rhead lecturing to the surgeons and barbers in Monkwell-street at their hall—good artists, as they called themselves, sound practitioners as we should say, differing from their professional descendants of to-day in the fact that instead of thinking, as I find most of my surgical colleagues do, that nearly all diseases, whether internal or external, are curable by the knife, they were inclined to administer medicines with which they were imperfectly acquainted and which the law forbade them to use.

If we cannot forget the words of Hippocrates and the sceptre of Dr. Caius which are exhibited to us at every meeting, surely we must also remember Dr. John Lawson of Queen's College, Cambridge, our President in 1694, who gave us the handsome mace which is borne before the President.

We are quaintly reminded on the *postridie palmarum* of the devotion to our College of Dr. Baldwin Hamey, one of our largest benefactors, when we each receive from his estate half-a-crown. No one has ever surpassed him in his love for the College and admiration of Harvey whom he knew in the College for more than 20 years. In 1625 he went to Hastings on his way to Holland. He had supper with the mayor who dreamed afterwards that Hamey should be detained, and set a guard at his inn. He was thus unable to join the vessel when she sailed; a sudden storm within an hour caused the ship to founder with all on board, and thus the mayor's suspicions, which, perhaps, arose from the learned character of Hamey's talk at his table, saved his life. He was a loyal man and gave the King a valuable ring at the Restoration which he had bought at the sale of King Charles I.'s effects, and in justification of his occasional attendance at the sermons of the Commonwealth men it is mentioned that he used to read an Aldine Virgil bound in vellum or a little Aristophanes bound in red all the time.

Charles Goodall, President from 1708 to 1712, was another man devoted to the College and a zealous defender of its privileges. We who have known the labours and the fidelity of Sir Henry Pitman and Dr. Edward Liveing in the College of our time can have no difficulty in the grateful remembrance of a similar man in the past. He was a friend of

<sup>12</sup> Henry Lyte, a New Herbal London, 1619.

Sydenham who admired both his character and his skill and dedicated his "Schedula Monitoria" to him.

Sir Hans Sloane, our President from 1719 to 1735, was thought worthy to succeed Sir Isaac Newton in 1727 as President of the Royal Society. The μεγαλοπρέπεια of Aristotle, the generous splendour suitable to a great man, was displayed by him through a long life, and the institution of the British Museum was due to the discerning liberality with which he disposed of his vast and valuable collections at his death. Hans-place and Sloane-street appropriately preserve his memory on the estate which he had purchased and where he lived during 13 years of an intelligent old age.

Two recent benefactors must not be omitted. Sir Hermann Weber who founded in 1895 a handsome prize in memory of Dr. E. A. Parkes, and Captain Edward Wilmot Williams who founded a gold medal in memory of Dr. Francis Bisset Hawkins, his kinsman, long the senior Fellow of this College.

We are assembled in our library and must not forget those who have enriched it. To men who regard the world of books as a region only second to the world of men in its interest ours is a delightful collection. It is in great part composed of the successive gifts of men who have loved their books, and represents the reading of 12 generations of well-read physicians. Linacre our founder, and Dr. Holsbosch, and Gilbert, the discover of the magnetism of the earth, and the Marquis of Dorchester, friend of Harvey and of Scarborough, and Sir Theodore Mayerne, physician to Henry IV. of France and to James I., Charles I., and Charles II., a man of extraordinary learning and ability: these were some of the earlier benefactors. After them comes Dr. Richard Hale, whose portrait justly occupies a prominent place here. He was of Trinity College, Oxford, and though an enlightened and well-informed physician of his own time took pleasure in mediæval treatises, enjoyed the *Flos medicinae* of the School of Salerno, and walked with pleasure in the garden in which that flower grows beside the *Rosa Anglica* and the *Rosa Gallica*, perhaps murmuring as he went:

"Cur moriatur homo cui salvia crescit in horto?  
Contra vim mortis: non est medicamen in hortis."

Later still comes Richard Brocklesby, a schoolfellow of Burke and his friend throughout life. He was a generous giver: to Burke, to Johnson, to his nephew Thomas Young, one of our Fellows, the exponent of hieroglyphics, the originator of the undulatory theory of light, to our library, and I am sure in many other directions no longer remembered.

"What I spent I had,  
What I kept I lost,  
What I gave I have,"

says the old epitaph. Brocklesby understood its meaning. Johnson himself gave us a book and we owe a debt of gratitude to one other of that great literary circle, for Sir Joshua Reynolds went to much trouble for us as to the cleaning of our pictures. In later days Sir Andrew Clark gave a handsome bookcase filled with books, and Dr. Pye-Smith a fine solid case for the display of some of the treasures of our library. Our present librarian, Dr. Payne, has given several rarities from his own fine library to ours.

There have been endowed in the College at different times five lectureships. The oldest was founded in 1581 by Dr. Richard Caldwell and John, Lord Lumley. Caldwell, an Oxonian, was President in 1570. Only one of his writings has survived, a translation of the *Tables of Surgery* of Horatius Morus of Florence, and his ornate tomb, described by Camden, perished with the church of St. Benet's, Paul's Wharf, in the Great Fire of London, so that the lectureship is the chief memorial of his learning and virtues. John, Lord Lumley, was not unworthy to be his associate. He was of Queen's College, Cambridge, and had a noble library, parts of which are preserved in the British Museum, in the Bodleian and in the Public Library at Cambridge; and he wrote a translation of the *Institution of a Christian Prince* of Erasmus. The conversation in Lumley Castle must have been interesting, for its lord besides his knowledge of books had taken a part in many affairs of State and his wife, daughter of the twelfth Earl of Arundel was as learned as her lord. She translated the *Iphigenia* of Euripides and some orations of Isocrates into English and one oration into Latin. The founder of our lectureship died in 1609 and was buried in the aisle which he added in 1592 to the church of St. Dunstan at Cheam.<sup>13</sup> The inscription traces on his tomb

his descent from the times of King Edward the Confessor, and in its marble ornament with 19 surrounding shields of arms showed how fully he, whose father was attainted and executed at Tyburn, had restored the ancient wealth and honours of his family.

The next lectureship is that founded in 1632 by Dr. Theodore Goulston, a Fellow of this College, who was educated at Merton College, Oxford. He was a person of much learning and translated into Latin with commentaries two books of Aristotle and several of the *Opuscula* of Galen. He lived in the same parish as Harvey, that of St. Martin-by-Ludgate, and as he was Censor in the year in which Harvey was appointed Lumleian lecturer, while they were Censors together in a later year, knew him well. The rector of their parish was Samuel Purchas, editor of "*Hackluytus Redivivus* or Purchas his Pilgrims," and it is easy to imagine that this Johnian who had been at Cambridge during Harvey's time there, was now and then admitted to the society of Goulston and Harvey and perhaps amused them with tales from the records of voyages of which he possessed the manuscripts. Goulston's "*Opuscula Varia*" of Galen was published by his friend Thomas Gataker in 1640, after the editor's death. Harvey possessed a handsomely bound copy, now in the British Museum, in which he has written many notes, especially on the *Exhortatio ad Medicinam et Artes*, the *De Sectis ad Tyrones*, the *De Cognoscendis et Corrigendis Animi Perturbationibus*, and the other two treatises on the mind.

A third lectureship was planned by Dr. William Croune, a Fellow of the College, in 1684, and was formally established by his widow in 1706. He had been a Fellow of Emmanuel College, Cambridge, and became professor of rhetoric at Gresham College and read several papers before the Royal Society, of which he was one of the earliest Fellows.

No further lectureship was founded till 1880 when the widow of Dr. William Wood Bradshaw, a Member of the College, founded an annual lecture in memory of her husband.

In 1886 Dr. Gavin Milroy, a Fellow of the College, founded a lectureship in State Medicine and Public Hygiene.

These five lectureships are devoted to clinical medicine, pathology, anatomy, physiology, and public health, but neither here nor in any of our universities are there public lectures on the history of medicine. The history of medicine may, perhaps, be divided into three parts. One belongs to the general study of philosophy, the exposition of the theories and the arguments to support them which have been used in past ages. This is chiefly of interest in relation to the study of the human mind. A second part treats of the lives and the work of physicians of past times. This cannot but instruct us who have the same difficulties and the same objects. The third is the study of the cases and epidemics of past times as they appear not only in medical writers but in general history. This is, perhaps, the most useful of all. In the mistaken interpretation of accurately recorded phenomena in old times we have before us a picture of our own errors in the interpretation of what we discover at the bedside and a warning against too great deference to prevalent systems of treatment. To learn anything from the history of medicine in any of these branches it is first necessary to know medicine, and the only valuable writers on the subject have been well-informed physicians like Dr. John Freind, whose history of physic is the most considerable work on the subject in our language, or Dr. Payne, whose devotion to pathology and to clinical medicine is as well known as his lucid exposition of the learning of past centuries. It is fortunate that the opportunity has occurred of establishing such lectures.

The wife of a very learned man desires to perpetuate his memory in a way grateful to him by the foundation in this College of a lectureship on the history of medicine. He was a Member of the College and she wishes that the benefaction shall be considered to come from him and be called after him as in the case of Dr. Croune, whose wishes as to a lectureship were carried out by his widow, Lady Sadleir. No occasion seems more appropriate than this to mention to the College this gift of a sum of £2000 to be invested in the usual way for this purpose on conditions similar to those of our ancient lectureships, which must, of course, be formally laid before our Comitia, and will, I do not doubt, be accepted there, since when I lately mentioned them by letter to the Comitia Minora I was informed that the President and Censors, though without formal authority in such a case, were prepared to recommend the College to accept the gift.

<sup>13</sup> Now detached from the church.

Dr. Thomas Fitz-Patrick, who must hereafter be mentioned as one of our benefactors, was born in 1832 at Virginia, a little country town standing at the end of a long lake in Cavan. Although one of the least wealthy parts of Ireland the surrounding district is one of literary fame. In the boyhood of our benefactor the epigrams and other poems of Philip MacBradaigh, and his touching lines on his daughter's affection, were known to everyone, as well as those of his kinsman Fiachra MacBradaigh, a country schoolmaster of ready wit who flourished in the reigns of George I. and George II. The itinerant fiddlers and pipers who had taken the place of the harpers of more remote times all knew the songs of Cathair MacCaba, who died in 1740 and was a harper as well as a poet and a friend of O'Carolan, the most famous of all Irish musical composers, who addressed to him a pleasant poem—"Rath do cheirde fein ort" (here is the reward of your own art). The ancient churchyard of Moybologue in which MacCaba is buried contains also the mortal remains of Brian O'Clery, a somewhat later poet of the same century, descended from a famous race of hereditary historians whose chronicles are one of the chief sources of information about mediæval Ireland. His poem on spring and others of his verses were often recited and his early death lamented. John O'Neachtan's poems on the death of Mary of Modena, Queen of James II., and on the Duke of Berwick, and many other compositions of his, circulated in this district. John O'Farrelly of Mullagh, a village about four miles from Fitz-Patrick's birthplace, where he first practised his profession, wrote the history of the district under the title of "Seanchas an da Bhreifhne." A romance by Brian O'Reilly, entitled "Eachtra Mheic na Mhiochomhairle" (the adventures of the son of evil counsel), was read or repeated by great turf fires in many farm-houses on winter nights, though such in Fitz-Patrick's youth was the poverty of the district that even rushlights were rare and a splinter of bog fir or twigs of dry furze thrown into the fire supplied the light by which all these writings were read from manuscripts. It is right to mention these authors and their works—obscure elsewhere but long well known in that part of Cavan—in order to show how much love of literature there was, and I agree with that great scholar, the late Mr. Henry Bradshaw, in respecting the ill-remunerated scribes who copied these works in manuscript and the authors who composed them without hope of other reward than local fame. Nor were the literary associations all in the native language, for Henry Brook, author of "The Fool of Quality," a novel once widely read, lived at Corfada, between Virginia and Mullagh, as did his accomplished daughter, Miss Charlotte Brook, whose "Reliques of Irish Poetry" is a handsome quarto to be seen in most good eighteenth-century libraries. Close to Virginia is Quilca, the home of Dr. Thomas Sheridan, the editor of "Perseus," where Swift was a frequent guest, and many stories of the famous Dean of St. Patrick's were current in the neighbourhood in Fitz-Patrick's youth and later. In the next field to the fragment of wall which is at the present day all that is left of the house of Henry Brook a small but ancient cairn near a disused well marks the birthplace of a learned person of very ancient times—St. Cillian of Würzburg, in the seventh century the apostle of Franconia. The varied literary associations of his native district had no doubt a great effect in giving Fitz-Patrick a taste for literature of all kinds. He graduated at Trinity College, Dublin, where he obtained several prizes, and became a Member of this College in 1868. He was a man imbued with learning, well read in Homer and in Lucretius, and knowing Spanish, Italian, and French, and German, as well as something of Hebrew, of modern Greek, and of Danish. His knowledge of English literature was extensive and his taste good. He had travelled as well as read and having thus accumulated all the materials for conversation he was a delightful companion. His intellectual attainments were the ornaments of solid virtues and he deserves to be remembered with honour in this honourable place.

I could mention many more worthy benefactors and, as in private duty bound, you, Sir, and the Fellows would sit on till I had ended their praises, but I must remember that we have guests who may exclaim with Macbeth :—

"What! will the line stretch out till the crack of doom?"

So, like an old charter, I will end my list with the words "cum multis aliis." We are grateful to them all and will always maintain their fame.

As to the last parts of Harvey's exhortation how can they

be better carried out than by considering the examples of the investigation of nature and the maintenance of friendship which the College itself affords. Harvey himself first of all, beloved in his time, untiring in his observations, considering them and stating their results in every aspect during all the years from 1616 to 1628, and ending in the certainty that the blood in the animal body is impelled in a circle and is in a state of ceaseless movement—that this is the action which the heart performs by means of its pulse and that this is the sole end of the contraction of the heart. Think how the pulse had been studied before, in the 13 books of Galen, by Rufus of Ephesus, by Philaretus, and by many more, yet never understood because an hypothesis resting on too small a basis of observation prevented men from seeking out the truth of nature by way of experiment. Then Francis Glisson labouring for five years and more at the observation of a disease undescribed before and ending with a perfect pathological and clinical treatise on Rickets, the first of its kind to appear in England. And Heberden, whose commentaries, though they contain no single great discovery, yet are so original in every line that they are a continued discovery of all that may be seen at the bedside. Sir George Baker, working out the causes and the results of lead-poisoning in the cider country and leaving no step unassured on the way. Sir William Jenner laboriously working at the bedside and in the post-mortem room and by the method which Harvey urged, "*αυτοψία non mentis agitatio*," demonstrating the true character of enteric fever and its distinction from the typhus fever with which it had so long been confounded.

Many of my predecessors have dwelt at length on the discoveries of Harvey himself. I should like to have done so, too, had I not felt bound to follow his own injunctions and to commemorate our benefactors, a task perhaps easier to perform, for it requires great talents to frame a composition worthy of his fame and to be so great a master of words as to utter praises equal to his merits who left us so great a discovery won by his own genius. The lines of Lucretius on Epicurus may justly be used to praise Harvey :—

"Quis potis est dignum pollente pectore carmen  
Condere pro rerum maiestate hisque refulis?  
Quis valet verbis tantum qui fingere laudes  
Pro meritis ejus possit qui talia nobis  
Pectore parva suo quesitaque præmia liquit."

## An Address

ON

## EXAMINATIONS AND THE EDUCATION OF THE SPECIAL SENSES.

*Delivered at the Queen's Hospital, Birmingham, on Oct. 18th,  
1901, on the First Distribution of Clinical Prizes  
since the University commenced its work,*

By THOMAS BRYANT, M.CH., F.R.C.S. ENG.  
AND IREL.,

SURGEON-IN-ORDINARY TO THE KING; CONSULTING SURGEON TO QUINT'S  
HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF  
SURGEONS OF ENGLAND, ETC.

MR. PRESIDENT AND GENTLEMEN,—You have but recently enjoyed the first Congregation of your ideal university and had the benefit of learning from your distinguished Principal the history of its birth. You have likewise had the benefit of hearing from your no less distinguished Chancellor and Father of the University the clear enunciation of the principles upon which the institution has been founded, with an eloquent expression from his parental lips of the brilliant career which it is anticipated the university will run in the coming ages.

As an interested worker and dweller in a city older than Birmingham, which is now seriously and strenuously occupied in working out the problem of turning a mere examining university into a teaching one for a population many times larger than your own, I have studied all your proceedings, and as the President of your Clinical Board has been so kind as to ask me to distribute the clinical prizes to the students at this hospital on this the first occasion since

Birmingham received a charter for its university I may be pardoned for making a few remarks upon your ideals and hopes of future developments.

First of all I must congratulate you upon having adopted in your modern institution the high ideals of the venerable universities of this country of which we all are so proud. It was a wise decision for you to have taken, for to build upon such a solid basis your foundations must be firm, and by so doing opposition will certainly be disarmed against your efforts "to strike out some new path of distinction which will be not unworthy of their companionship." For the founders of your University have clearly been alive to the fact that different stages of human progress call for changes in new as well as in old institutions, so as to adapt them to the requirements of the times in which they live.

To lay down in the first place the principle that in such an ideal institution as this "all existing knowledge is to be taught" was absolutely correct, in spite of the probability that in carrying it out great demands may be made upon your resources, although you have good reasons to anticipate a realisation of your ideal, based upon past experience and the unprecedented success which has attended the foundation of your University.

The second feature of your ideal university—"that it is a place where the knowledge which has been acquired has to be tested"—is as sound as the first, although in carrying out the principle much discretion with care is needed, for whilst all will admit that too many examinations encourage cramming and discourage individual effort, such examinations as are given should always be searching. Periodical class-testing by teachers may be wise and necessary in order to mark progress, but all examinations, and particularly oral examinations, for degrees and honours should be undertaken by outside professors of experience in the presence, and with the assistance, of the university teachers. As an examiner of some experience and as a visitor of examinations conducted upon methods widely differing I have no hesitation in expressing my conviction that whilst with every method of conducting examinations wrong decisions will occasionally be given, the chances of giving them are unquestionably far fewer by the method I am now advocating than they have been where the examinations have been entirely conducted by the teachers themselves. By any and every method of examination good or well-prepared men and badly-prepared men can be recognised with equal facility, whereas with the intermediate and largest class, which includes the indifferently-prepared student, the difficulty of decision is always great. With such a class it may be true, as I have heard it stated, that the greater popularity of the teaching examiner over the outside examiner is not open to a question, and as a visitor of examinations I can well understand why such a consensus of opinion should exist, for I could, if I deemed it prudent, afford you much food for thought and some amusement by recording incidents illustrative of such methods as might seem to explain the student's view. But, seriously, is it a true subject of congratulation for an indifferently-prepared student to have just scraped through his examination? and is such a success a true subject of congratulation from a university point of view? From both points of view I unhesitatingly answer that it is not, and in saying this I have from the university standpoint the support of your Chancellor when he stated: "I conceive that common prudence should teach us to keep up the value of the degrees which we have begun to confer to-day, and nothing would be more unwise, more fatal to our reputation and to our ultimate success, than that we should endeavour to multiply the number of our students at the expense of their quality." From a student's point of view the same conclusion has to be drawn—at any rate, from the point of view of the medical student—for is it not true that many an indifferently-prepared student has developed into a good one by some throw-back for six months upon extra study? And that which was at the time looked upon as a calamity not only gave an impulse to efforts that had been half-hearted or torpid, but had helped to develop a character of a higher order and had rendered a successful career in life more certain. For my own part, when, as an examiner, a student whom I knew to be a good one was rejected in a pass examination my sympathies were more with his parents than with the pupil himself, who, in spite of his throw-back with its disappointments, had been given one more chance of taking advantage of his opportunities of gaining knowledge and experience in medical matters in his medical school which he was not likely to have again, for experience has certainly proved to me that

from a student point of view a temporary rejection is not always a matter to be lamented, since by it many a feeble man has been made strong and powers have been developed in him which have proved to be of lasting value.

With respect to the third feature of your University I can give nothing less than my warmest congratulations; for to start the University and to maintain it "as a place where knowledge is to be increased and where the limits of learning are to be extended" is a noble ambition; and when this object is to be sought by uniting the students with their teachers in the work of fresh and new investigation your aims are almost those of perfection, and if eventually they are but imperfectly realised they must prove a success.

Lastly, we are told that your university is to be a place where the application of knowledge must be indicated and directed and that theory and practice are to be combined with due regard to the needs of your own time and of your own district, and that to carry out these wisely-conceived and well-considered objects you look with confidence to the help of your fellow-citizens. That you will not look in vain for this assistance is my firm belief and hope, and if you as the medical faculty of this enlightened University can but secure, in the words of your Chancellor, "the establishment of a great school of medical research which could carry forward and apply the discoveries of the last few years—discoveries which indicate to us, at any rate, the direction in which we are to seek for the weapons wherewith to combat suffering and misery and disease," you will, indeed, excite the envy of all rival institutions, for if theology is what it is said to be by the Bishop of Calcutta, "the queen of the sciences, because of the power of her facts as applied to human life and its needs," surely the profession you have adopted must claim to be the king, since it is the one art and science which is utilised for the special benefit of mankind and which culls from every branch of human industry and knowledge anything and everything which can possibly have a beneficial influence upon the prevention, relief, or cure of human suffering or disease. Under such circumstances, how wise it is that this faculty of medicine should be part and parcel of a university which is based upon the four leading principles upon which I have commented and where all knowledge is taught, tested, increased, and applied.

There is, however, one important branch of education which your teachers, however skilled, can do no more than encourage and which consequently must be left practically in your own hands. It can neither be imparted by lectures nor acquired by reading "through the spectacles of books," and yet it is without a doubt the chief accomplishment upon which your success in this university and later in the practice of your profession will unquestionably depend. I allude to your individual power of intelligent observation, through which your personal experience must be acquired, as secured by the education of your special senses of sight, hearing, and touch with your powers of reflection upon the facts which your senses have supplied you. I should add that if a student cannot be taught this he can be educated to acquire it by those responsible for his education.

How the senses are to be educated is a personal matter; if they have been partially trained or disciplined in early life by the study of some branch of natural history after the manner of John Hunter, or in one of our public schools where science is recognised, as may have been the lot of a few of you, you will under either of these circumstances have gained an advantage of great value over your fellow-pupils who have been less fortunately placed, for such will soon have discovered how difficult it is, even in early manhood, to make up for the deficiency of their primary education; and yet it has to be done; for as medical students you will have found out that to gain any success worth having a degree of keenness and adaptability of sight, hearing, and touch is absolutely essential, and that to acquire eminence such keenness must not only be of a high order but it must be associated with an intelligent appreciation of the fact observed. To attain the degree of intelligent observation which is so essential for the practitioner of medicine may be a task of difficulty. Some students never acquire it. Those who do so in a high degree are amongst the best, but there must be many degrees of efficiency, and I want to help you in the solution of this problem out of the somewhat extensive opportunities I have enjoyed of teaching, testing, and investigating, and in so doing I must ask my younger hearers to put into practice what I may suggest and your younger

teachers by testing your capabilities to help you in your efforts. To my senior hearers I venture to apologise for having taken upon myself under present circumstances the rôle of a teacher and to ask them to explain my action by the confidence I have in the value of the recommendations I am about to bring before you. In your hands, however, I feel sure of support, for your experience will certainly justify the action I am now taking.

As scholastic conditions exist at present the education of the senses has in school life, unfortunately, been left to chance, and no special means have been introduced into school routine for their education. In university life the introduction of some branch of natural science as a preliminary subject of study has been an educational advance of great importance, not only as an introduction to the knowledge of Nature's works, but as a means of demonstrating the value of modes of investigation which are applicable to every branch of human research. Under all circumstances, however, the education of the special senses should be a leading object of all teachers, and the best way of carrying out this purpose in medical education is by testing the student's capabilities. The bulk of the work, it is true, must be left to the students themselves, but still they can be encouraged, and by being so will surely be materially helped. A medical student may watch with every care an able teacher in his endeavour to unravel the intricacies of a complicated case of disease, but he will not gain much by his observation, for he cannot see, hear, or feel with his teacher's senses, but can only do so with his own; and when he has advanced far enough to consider the meaning of a diagnosis he will have discovered that a reliable one can only be the outcome of a correct observation of the facts of the case as brought out by his own observation and the conclusion of sound reasoning upon the facts themselves.

How, then, it may be reasonably asked, is a student to learn how to make the best use of his senses for medical purposes? There is but one answer, and that is by steady and prolonged practice—and this practice must be established on a method. Let the student, as a rule of life and as a matter of routine, habitually begin his investigation of every case by looking well at his patient *as a whole* and subsequently in detail, and as he progresses in the powers of observation he will be astonished and pleased to have discovered how much may be learnt by a look and how valuable the intelligent look has been. In local injuries and diseases let him follow an equally valuable routine practice and as a matter of habit invariably compare the injured with the corresponding uninjured part, and having noted the facts observed with the points of difference in the two sides of the body let him reflect and reason upon the value of the facts—indeed, upon the value of each fact. By such a routine practice a provisional diagnosis may have been reached which has either to be supported or refuted by subsequent inquiries into the history of the case and any other facts which may have been elicited by manipulation and the sense of touch. In all cases let sight lead the way and touch follow, reflection governing the whole. In a large number of cases it will be found that the objective facts elicited by sight are alone enough to suggest a diagnosis, which has only to be supported by the points afforded by the history of the case and the facts brought out by manipulation and palpation. In local injuries or diseases a student is too apt to commence his examination of a case by manual methods, much to the detriment of his patient and his own discomfiture; this natural but inefficient routine ought not to be allowed, for as a rule a good inspection of the injured or diseased part and its comparison with the sound side will supply suggestions as to the nature of the case which will only require the gentlest manipulation of the surgeon to confirm, the diagnosis of the case being based upon the facts seen and felt, the history of the case, and the exercise of thought upon the facts. Examiners will greatly help the establishment of this habit of investigation by asking pupils primarily to look at a case and to describe what they see before they are allowed to use their hands. I would suggest, in order to assist self-help in the education of sight, that house surgeons, fellow-dressers, and clinical clerks examine each other in any given case as to what they see; and argue out the probabilities of the nature of the case upon the points observed; and having done so to proceed to their investigation of the affected part by manipulation or other necessary methods. I would likewise ask the junior teachers of the schools or university to encourage such efforts, for as an old

teacher I can speak strongly in favour of them as well as of their efficiency. Indeed, by acting upon this suggestion fresh pleasures will be added to study, for students readily recognise the value of the method of approaching a case in the way I am advocating and find a pleasure in the recognition of the existence of a power of observation which had been dormant and which yields pleasure and profit by its cultivation. As an examiner I can likewise give strong testimony to the importance of this method of testing knowledge, for at the Royal College of Surgeons of England, where I commonly employed it, it was most instructive, and I can recall the interest which my old friend and fellow examiner the late Sir George Humphry took in the proceeding and how in his enthusiasm he subsequently took it to Cambridge and embodied the value of the method in his well-recognised precept, "Eyes first, hands next, and tongue last." I may add that it was in the differential diagnosis of a scrotal swelling that I first realised the full value of the method I am inculcating, when I, indeed, demonstrated that a student could by the eye alone, by this process of elimination, reach a provisional diagnosis of the case before him, which had only to be confirmed or confuted by manipulative methods, a history of the case, and the exercise of reason.

To dwell upon the value of the sense of touch is surely unnecessary; the *tactus eruditus* of the skilled surgeon is always a wonder to the uninitiated and is only to be acquired by much practice. In learning it I would impress upon the student that it can be educated as quickly by gentle manipulation as by the reverse, and that anything like roughness should always be avoided. To appreciate the significance of feeling the pulse is likewise the product of great practice and much thought. To estimate the presence or absence of tenderness in any part, and particularly in the abdomen, is always difficult, but in all circumstances gentle pressure is more likely to elicit the required information than severe pressure. In my own practice I have found a method of examining a sensitive patient upon this point of such great value as to induce me to describe it to you. I simply place my hand upon the part involved and tell the patient to press upon it with his or her hands until pain is produced; by so doing I can do no harm but learn much, and I am often startled by the greater amount of pressure a patient will by this method endure than I should have ventured to have employed.

With these suggestions to help you in your clinical work I must bring my remarks to a close. I have appreciated very highly the compliment you have paid me by inviting me to give away the prizes upon this the conclusion of the first academic year of the medical school of your new university; I recognise to the full the sound and liberal principles upon which your university has been founded, and congratulate you, your townsmen, and particularly your Chancellor, upon the energy and triumphant skill with which its establishment has been accomplished. I can now only wish you all God-speed in your work. It was from such feelings that I have been led to give you the few practical hints which the active work of a fairly long life has enabled me to formulate, to help you in the difficult task of educating your special senses, upon the successful use of which your future success in life must materially depend; they may to some of you seem trivial and unworthy of a great occasion, to others they may appear worthy of a trial, to a few they may seem sound. They form, at any rate, the first attempt to supply a great want and to educate systematically the special senses of medical students by methods which have been proved of value in general clinical work, for they have been tested somewhat extensively both in teaching and examining and are as valuable to examiners and teachers as to students. If I were a Rip van Winkle and could revisit this infant university 100 years hence I should probably find that these suggestions of mine, having done some good, had been incorporated into general teaching methods, and that as natural science had become part of general education the special senses of all students would have been cultivated far more efficiently than they can be said to be at the present time. I should certainly find this University possessing a history as proud as any of its pre-ent compeers, and with future prospects bright enough to satisfy the minds of the most hopeful of its present founders. What Birmingham itself would have become by "the application of the highest science to its commonest industries and manufactories" I will not venture to predict, for the mind can now hardly realise the possibilities which open out from such a point of view. As to medical science, the applied science of all the arts and

sciences for the benefit of man, such would certainly be still in existence, but how can we picture its position? for by preventive medicine, the use of antitoxins, and the influence of friendly bacteria many of the diseases which at the present day are most destructive will probably have been cleared away, the art of living have become more perfect, and the art of curing not have taken a back place. Life and death will, however, still be present, and men and women with the same natures as now exist, although under altered and possibly improved conditions. New diseases, or old ones so modified as to seem new, may have come into existence as moulded by the altered circumstances of life and encouraged if not brought about by the use of peptones, pharmaceutical fancies, self-drugging, and refinements of daily life. Hope of higher things would not have departed, for Birmingham University, with others like it, would still be in existence and be doing their beneficent work to make life more useful, more profitable, and therefore happier.

I thank you, gentlemen, for your attention and in the words of your Chancellor close these remarks with "*Floreat universitas nostra.*"

#### ABSTRACT OF

### Presidential Address

ON

## THE DECLINE IN THE ART OF PRESCRIBING.

*Delivered before the St. Mary's Hospital Medical Society on Oct. 16th, 1901,*

By ARTHUR P. LUFF, M.D., B.Sc.,  
F.R.C.P. LOND.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS AND LECTURER ON FORENSIC MEDICINE IN ST. MARY'S HOSPITAL.

GENTLEMEN,—The subject that I have selected for my address to you this evening is the decline in the art of prescribing. It is a subject which has given me cause for much painful reflection for several years, and it is one which, in my opinion, affects very closely the welfare of the public as well as the usefulness and dignity of the medical profession. I think there cannot be the slightest doubt but that the art of prescribing—that is, of ordering suitable remedies in suitable forms for the treatment of morbid conditions—is declining, and that this very important function of the medical man is being replaced by what I consider to be the slovenly and enervating habit of writing an order for some proprietary preparation or for some compressed form of drug, and then dignifying such an order with the title of a prescription. There is, I think, a tendency at the present time in this era of brilliant discoveries in medicine, pathology, and bacteriology, and in this age of splendid advances in surgery, to neglect the treatment of common and of minor ailments by drugs. Let me, however, impress upon you that in the treatment of such ailments lies the principal part of your work as medical practitioners, and that the gauge by which your success in practice will be mainly measured, and the esteem in which to a great extent you will be held by your patients, will depend upon the success you attain in the treatment and cure of what may superficially appear to be but trifling ailments, but which, none the less, as departures from ordinary health are naturally considered by the individual sufferers as important, and therefore as deserving the careful attention and the skilled therapeutic resources of the medical man.

In my opinion the main reasons for the present decadence in the art of prescribing are the altogether inadequate attention which is given to the teaching of the subject by the majority of the members of the staffs of the various teaching hospitals, and the scanty test applied by so many of the examining bodies as to the possession of a knowledge of rational prescribing on the part of candidates presenting themselves for the final examinations. The want of attention which is given to the teaching of the subject in our large hospitals is certainly, as far as the out-patient

department practice is concerned, in some measure due to the over-pressure of work consequent on the number of patients that have to be seen and treated in a given time—an over-pressure which necessitates, to some extent, the ordering of medicines already prepared according to some formula in the hospital pharmacopœia. The prescribing of these ready-made medicines undoubtedly saves the time of the physician or surgeon and of the dispenser, but, unfortunately, the outcome of the custom of ordering ready-made mixtures, &c., is that the students soon fall into the habit and carry it with them into private practice. Consequently they have no opportunity of acquiring confidence in their own powers to write a useful prescription and so fall a ready prey to the temptations offered them by manufacturers to prescribe some ready-made proprietary medicine or some form of a compressed drug. It has been stated that the hospital practice of ordering mixtures, pills, &c., by the titles under which they appear in the hospital pharmacopœia is not detrimental to the acquisition of a knowledge of correct prescribing, since the student can always refer to the pharmacopœia for information as to the composition and strength of the medicine ordered. I, however, strongly maintain that the information so obtained is in no sense comparable to the educational advantages of hearing the dictation of a prescription in full. There is no better method of acquiring a knowledge of correct dosage, and of the avoidance of incompatible ingredients, than by hearing the physician or surgeon dictate his prescription, comment on the dosage of the ingredients, and give his reasons for the employment of such ingredients. On the other hand, if it is left to the student to look up the composition of a medicine from the hospital pharmacopœia he is apt to forget to do so, and certainly he can never in that way either acquire a tithe of the knowledge, or retain the information so well in his memory, as by hearing the dictation of a prescription in full.

What I wish to impress is that in order to learn thoroughly the true art of prescribing it is essential, in the first place, that when you proceed to your hospital work you should give a regular and full attendance to the work in the wards and out-patient departments, and, secondly, that your teachers should recognise the importance of imparting to you a knowledge of correct prescribing for the individual cases before you, and should abandon, to some extent at all events, the set habit of ordering the ready-made medicines. Here I must touch upon what I consider to be a serious obstacle to the adequate attendance on the practical work I am advocating. I refer to the altogether unnecessary amount of time that you are required to give to so-called systematic courses of lectures. It is no uncommon experience for me when engaged in my out-patient room in the practical teaching of the diagnosis and treatment of disease, to see the students at a certain hour trooping away—unwillingly, I trust—to the set lectures which they are compelled to attend in order to be signed up for their examinations. Most cordially do I endorse the hope recently expressed by Dr. P. W. Latham, in his admirable opening address at St. George's Hospital, that the time may not be far distant when systematic lectures on medicine, surgery, pathology, pharmacology, forensic medicine, &c., will be discontinued, and students will thereby be enabled to devote more attention to practical work and demonstrations. As Dr. Latham said, "Formal lectures on these subjects are the inheritance of an ancient system, the relics of a time when books were scarce, but the system lingers on and apparently will die hard." I earnestly desire to see the abolition of certificates of attendance on most lectures and to witness the licensing bodies taking the bold and honourable stand of ascertaining for themselves whether students possess the requisite knowledge, and ceasing to require the guarantee that candidates have sat through a given number of what possibly may be but dreary and uninteresting discourses. In medical training and learning I am a staunch advocate of the principles of free trade.

There is another aspect of the subject of prescribing to which I wish to direct your attention. The practice of writing an order for a particular form of compressed drug or for a proprietary preparation—for I cannot dignify such an act at the writing of a prescription—is apt to encourage patients to recommend such proprietary articles to their immediate friends who, in their opinion, are suffering from similar symptoms or from what they imagine to be a similar complaint. I need scarcely point out to you that what has been ordered as suitable treatment

for A may be remarkably bad for A's friends and may be productive of serious harm to them. Moreover, to look at the matter from another point of view, by giving your patients the opportunity of recommending these proprietary articles to their friends you are simply playing into the hands, and the pockets, of the manufacturers of those preparations, which are so speciously puffed, and with the samples and laudatory advertisements of which we are so profusely deluged. You may, perhaps, say that if you write an orthodox prescription for a medicine the patient is just as likely to recommend that to his friends. As an actual fact my experience is that such is not nearly so likely to occur as when a patient can name a proprietary article which can be readily purchased of any pharmacist or at any drug store. It is, I believe, the ready facility with which powerful drugs prepared in compressed and other forms are obtainable by the public that constitutes a very grave danger—a facility which is responsible to a great extent for the increasing practice of self-drugging, and I am much afraid that this state of affairs has been brought about by these preparations being so indiscriminately and so largely prescribed by medical men. It is simply appalling to witness the habit that has grown up of people keeping in their houses and carrying about in their dressing-cases compressed forms of powerful drugs which they employ to relieve pain either by taking them internally or by hypodermic administration, quite losing sight of the fact that the removal of the cause of the pain is much more important than the removal of the pain itself. Moreover, the temporary relief of pain frequently prevents the sufferer from seeking medical advice until the diseased condition which is the cause of the pain has become thoroughly established, and therefore more difficult to cure. In addition, the facility with which these forms of compressed drugs can be obtained and administered encourages that most evil of habits, the taking of narcotic drugs. Let me strongly advise you never to prescribe drugs of a sedative nature, such as antipyrin, antifebrin, &c., by such names, but by their scientific terms. For instance, order antipyrin as phenazone, antifebrin as acetanilide, and so on. In addition, never order them in compressed forms, but prescribe them to be taken in cachets or as powders. It is frequently my fate in my private consulting-room for patients to present for my inspection and supposed edification the so-called prescriptions of some of the very minor lights of medicine. These documents are frequently mere orders for some proprietary preparation possessing an outlandish name, the composition of which is generally absolutely unknown to the prescriber, whilst for its supposed therapeutic effects he has to depend on the statements of the manufacturer of the article. These orders are to me sad illustrations of the ease with which the writers have departed from the path of therapeutic righteousness—across each one there appears to my mental eye written the word "Ichabod." On the other hand, it has frequently been my privilege to see the prescriptions of one who certainly ranks amongst the greatest and most scientific of physicians that have graced the staff of this hospital, and it is at once apparent that each prescription has been carefully thought out and adjusted to the individual needs of the patient. To me these prescriptions, which are never debased by an order for a proprietary medicine, are grand therapeutic lessons.

In conclusion, gentlemen, let me beg of you to endeavour during your studentship here to cultivate by every means in your power a knowledge of the art of prescribing. Let me entreat you never to become the instruments by which your patients may be tempted to drift into the habit of self-treatment by compressed and other easily administered drugs—a habit which is tending to displace the true therapeutic art and which is tending to divert into the hands of purely commercial men that function which should remain the prerogative and the glory of the medical man.

**THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.**—The next class for the instruction of volunteer medical officers in the subjects of the proficiency examination will be held at 23, Cambridge-street, W., and will commence on Monday, Nov. 4th, at 5 P.M. Officers who wish to join the same should apply to the Senior Medical Officer, Volunteer Ambulance School of Instruction, at the above address.

## NOTE ON THE RESULTS OBTAINED BY ANTI-TYPHOID INOCULATION IN THE CASE OF AN EPIDEMIC OF TYPHOID FEVER WHICH OCCURRED IN THE RICHMOND ASYLUM, DUBLIN.

By A. E. WRIGHT, M.D. DUB.,  
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

I AM indebted to Mr. H. M. Cullinan of the Richmond Asylum, Dublin, for a detailed account of the outbreak of typhoid fever which occurred in that asylum in the autumn of last year, and for particulars with regard to the results obtained by anti-typhoid inoculation in connexion with that outbreak. From the materials above referred to I have abstracted the following narrative of events.

*Course of the epidemic.*—The first case of typhoid fever which occurred in connexion with the epidemic here in question came under observation on August 7th, 1900. From that date onwards to the end of December 54 cases of typhoid fever occurred among the patients and the nursing staff. The chronological distribution of these cases is exhibited in the following tabular statement.

August 7th to Sept. 6th	...	...	...	19 cases.*
Sept. 7th to Oct. 6th	...	...	...	8 cases.†
Oct. 7th to Nov. 6th	...	...	...	8 cases.‡
Nov. 7th to Dec. 6th	...	...	...	14 cases.‡
Dec. 7th to 24th (half month)	...	...	...	5 cases.§

\* Eight of these cases occurred among the nursing staff.

† One of these cases occurred among the nursing staff.

‡ Three of these cases occurred among the nursing staff.

§ All these cases occurred among the nursing staff.

*Particulars with regard to the anti-typhoid inoculations undertaken.*—Soon after the commencement of the epidemic Mr. Conolly Norman, the superintendent of the asylum, applied to me for a supply of anti-typhoid vaccine. This having been placed at his disposal a first batch of 45 patients was inoculated by Mr. Cullinan on Sept. 6th. When these had recovered from the effects of the inoculation another batch was taken in hand, until on Nov. 30th, after a series of 17 sittings, a total of 511 persons had been inoculated. The inoculations were carried out exclusively upon insane inmates below the age of 55 years. No member of the nursing staff underwent the operation. The dose of the particular vaccine administered was in each case 0.75 cubic centimetre, this being the dose which had been fixed upon as appropriate in the case of soldiers proceeding to South Africa. The symptoms produced by the inoculation are described as follows by Mr. Cullinan in a paper published in the *Dublin Journal of Medical Science* in July, 1901:—

The constitutional disturbance following the inoculation did not prove in any of the cases in my experience to be of great severity. In every case almost the temperature rose within a couple of hours, in some few instances reaching 103° and 104° on the day of operation, while 101° and 102° were common heights for it to attain. It usually fluctuated for a couple of days, coming down gradually from the maximum, and being generally normal on the third day. In every case operated on all the temperature records were kept. Except in the cases already specially mentioned patients were able to be up and about on the fourth day. The principal symptom was headache, from which 86 suffered, some of them very severely; vomiting or retching occurred in 63 cases; loss of appetite and refusal of food in 33; diarrhoea in two; rather severe prostration in three; four complained of abdominal pain; while stiffness in the back and soreness over the seat of inoculation occurred in nine and 22 cases respectively. The last symptom of soreness in the flank, where each patient was vaccinated, was not in any case accompanied by local manifestation beyond a slight redness of the part and some swelling.

In the light of the constitutional symptoms here described<sup>1</sup> and certain events to which attention is drawn below I think that a somewhat smaller dose of vaccine might appropriately have been prescribed by me. It must, however, be noted that the circumstances did not admit of two successive inoculations being undertaken, and no estimate could be formed as to how far the patients would at the time of inoculation be exposed to the risk of infection.

*Particulars with regard to the number of susceptible persons exposed to infection.*—Mr. Cullinan estimates that after excluding all patients above 55 years of age as insusceptible, the total number of susceptible persons exposed to infection

<sup>1</sup> The reference is to Cases 1, 2, and 6, reported below.

\* In this connexion vide THE LANCET, Sept. 14th, 1901, p. 715.

at the date on which the inoculations were begun may be fixed at 655; 541 of these were insane inmates, the balance of 114 being nurses. Of the former, as we have seen, 511 were ultimately inoculated.

*Number of cases of typhoid fever which occurred in the inoculated and in the uninoculated respectively after the commencement of the inoculations.*—On and after Sept. 6th 29 and seven cases of typhoid fever respectively occurred in the uninoculated and the inoculated groups. Before considering the question as to what was the relative incidence of cases in the two groups the circumstances of each of the seven cases which occurred among the inoculated may be briefly considered.

CASE 1.—The patient was discovered to be ill on Sept. 6th. "In this case," says Mr. Cullinan, "owing to an oversight, the patient's temperature was not previously taken, but was found to be 101° immediately after the operation, remaining high, and at once assuming the characteristic curve of typhoid fever." In accordance with the history this case may be transferred from the category of cases which developed in inoculated patients to the category of cases which developed in uninoculated patients.

CASE 2.—The patient in question was inoculated on Sept. 19th and developed the disease on Sept. 22nd. "This case," says Mr. Cullinan, "was found to have a normal temperature and was apparently in good health before inoculation. The temperature rose after the operation, but instead of going down in a few days persistently remained high and assumed enteric features almost at once. .... I think it may be concluded that she would have contracted the disease in any case." This conclusion that the patient had contracted the infection before inoculation would appear to be justified, inasmuch as the interval of two days usually covered by the febrile reaction produced by inoculation would appear to be much less than would be required for the incubation of the disease. None the less I have in the statistical table given below refrained from formally excluding this case from the category of cases occurring in the inoculated. I have contented myself with distinguishing it by the use of italics, brackets, and a note of interrogation from the other cases included in that category.

CASE 3.—"The patient in question was inoculated on Sept. 22nd, and on the 24th was quite well apparently, but on the 28th was found to have a temperature of 100° and a couple of doubtful spots. On the 30th there was a typical crop of spots. The case from that out *was a severe one* .... I would not [the quotation is still from Mr. Cullinan's paper] place this case definitely among those suffering from prodromal signs at the time of inoculation, but ..... as the spots began to appear six days after the operation I think we may fairly refrain from blaming the inoculation." In view of the possibility that the incubation period may run a shorter course in a patient who has in the meantime been subjected to inoculation it will be well to retain this case in the category of cases contracted subsequently to inoculation.

CASE 4.—The patient in question, a girl who had been inoculated on Oct. 3rd, having left the hospital three days after the operation, was attacked *very severely* on Oct. 15th. She was found on this day to have a crop of spots. *This patient died.*

CASE 5.—Inoculation was here performed on Sept. 22nd, and the patient, "who had been quite well in the interval," developed typhoid fever eight weeks subsequently "and was found to have a profuse crop of spots." Obviously there can be no doubt as to how this case is to be classified.

CASE 6.—The patient was inoculated on Nov. 12th and "was very ill after the operation, and continued so with a high temperature. On the 20th she had a crop of spots, having had all the appearances of typhoid in the interval." Mr. Cullinan feels disposed to regard this as a case in which the patient was sickening for the disease at the time of inoculation. This assumption seems to me justified in view of the short period which elapsed between inoculation and the development of the typhoid spots. The fact that the patient was "very ill after the operation" also points in this direction. None the less it will, as in Case 3 considered above, be preferable for the purposes of our statistical comparison to retain it in the category of cases contracted subsequently to inoculation.

CASE 7.—The patient, "a woman of about 50 years of age, operated upon on Nov. 5th, and getting over the effects in three days, was found on Nov. 17th with a temperature of 101°, and had a *very severe attack*, followed by a *relapse from which she nearly died*. I consider," says Mr. Cullinan,

"that on this case the serum—meaning thereby the typhoid vaccine—acted detrimentally and probably accentuated the severity of the attack."

Having in a very recent communication<sup>3</sup> discussed the general issue raised by Mr. Cullinan's comment, I may here leave the italics in the above protocols to speak to the attentive reader and proceed at once to summarise the results of the above analysis. That analysis has shown that of the inoculated persons attacked by the disease the *first* had certainly developed the fever before inoculation; the *second* had almost certainly contracted the infection before inoculation; and the *third* and *sixth* had also probably contracted it before inoculation. In the case of the *fourth* and *seventh* patients if the infection was, as would seem probable, contracted subsequently to inoculation it must have been contracted immediately afterwards, while the patients were still suffering from the effects of the operation. Thus the *fifth* patient would appear to have been the only one among the seven inoculated patients attacked who contracted the infection after the clinical symptoms due to the operation had passed off. Let us, however, for the purposes of our statistical comparison, admit that the last five, or even the last six, of the seven inoculated patients who were attacked may have contracted the disease subsequently to inoculation.

*Manner in which a comparison can be instituted between the incidence of cases in the inoculated and in the uninoculated.*—Our task will, then, be to express in the form of a valid comparison the fact that out of a body of 655, who consisted in part of inoculated and in part of uninoculated persons, five—or if we include Case 2 mentioned above, six—cases of typhoid fever occurred in the inoculated, while 30—or if we exclude Case 2 just referred to, 29—cases occurred in the uninoculated.

The first point which comes up for consideration in this connexion is the question as to whether the 114 uninoculated nurses who are included in the total of 655 susceptible persons were exposed to a greater risk of infection than the insane inmates. If they were not exposed to greater risk they may obviously be included among the "controls." In connexion with the risk incurred by the nursing staff Mr. Cullinan writes that "none of the nurses who contracted the disease contracted it by attendance on inmates suffering from enteric fever. All the nurses attacked were ordinary divisional nurses who spent their days in the same room as the inmates and for the most part slept off the dormitories, being in all respects as liable to infection as the inmates, except in the respect that sane people have, from the point of view of the risks undergone by them, in my opinion, a considerable advantage over the insane." It may, therefore, be taken that the nurses were at any rate not exposed to greater risks of infection than were the patients, and hence the figures relating to these may, equally with the figures relating to the uninoculated insane, be utilised for the purpose of instituting a comparison between the inoculated and the uninoculated. The complete data which have been furnished to me by Mr. Cullinan admit of two such comparisons being instituted. The first of these comparisons is a comparison between the number of cases occurring subsequently to the date of the completion of the inoculations in 504 inoculated persons<sup>4</sup> (insane inmates) and 114 uninoculated persons<sup>5</sup> (nurses). This comparison is as follows:—

*Number of Cases occurring in the Uninoculated and Inoculated respectively in the interval between the Completion of the Inoculations on Nov. 30th and the Development of the Last Case of Enteric Fever on Dec. 24th.*

	Number of persons under 55 years of age under observation.	Number of cases.	Number of deaths.
Uninoculated ...	114	5	0
Inoculated ...	504	0	—

The comparison in question brings out in a striking manner the comparative immunity of the inoculated; it is, however, robbed of a great deal of its interest by the fact that the

<sup>3</sup> THE LANCET, Sept. 14th, 1901, p. 715.

<sup>4</sup> This number is arrived at by subtracting the seven inoculated patients who developed the disease from the total of 511 who were inoculated.

<sup>5</sup> The number of nurses was kept up to 114 by replacing those attacked by the fever.

period of observation which is covered by the comparison is here a very short one. A comparison based on the average daily strength of the inoculated and the uninoculated will, therefore, be of greater interest, covering as it does the whole period of three and a half months from the commencement of the inoculations to the termination of the epidemic. For the purposes of such a comparison Mr. Cullinan has kindly furnished me with (a) the number of patients operated upon by him at each sitting and the dates of these inoculations; (b) a list of nurses and patients attacked with typhoid fever; and (c) a list of patients who died from other diseases or who were admitted or discharged during the period of observation. The third document may be left out of account as it shows that the number of individuals of a susceptible age who were admitted or discharged or who died from other diseases during the period of observation was so small as to be incapable of exerting any appreciable effect upon the general result. Having simplified our task in this way, we arrive at the number of the inoculated and uninoculated on each successive day by taking into account (a) the alterations in the number of the inoculated and uninoculated brought about by the successive inoculations and (b) the alterations in these numbers brought about by the development of typhoid fever in members of each group. Taking the numbers thus arrived at we now multiply in each case by the number of days during which that particular strength was maintained. Finally, we add together the figures relating to each group and divide in each case by the number of days included within the whole period of observation. In this manner we arrive at a daily average strength of 339 for the inoculated and of 298 for the uninoculated. We now institute our comparison by dividing the number of typhoid-fever cases which occurred in the inoculated and uninoculated groups respectively into the average strength of each group. Before considering the statistical result thus arrived at it will be well to realise why we are here justified in regarding a result obtained in the manner which has just been indicated as the result which correctly represents the relative incidence of typhoid fever in the inoculated and uninoculated groups. We shall realise this if we consider what is the assumption to which we are committed by the method of calculation here adopted. That assumption is that the cases of typhoid fever among the inoculated would not have been more numerous if the number of inoculated had stood throughout at 339 instead of standing, as it in reality did, at a lower figure on all dates previously to Nov. 5th and at a higher figure on all dates subsequently to this particular day. Now this assumption is manifestly justified if the risk of contracting typhoid fever was as great in the period between Nov. 5th and Dec. 24th when the inoculated numbered more than 339 as in the period between Sept. 6th and Nov. 5th when the inoculated numbered less than 339.

Mr. Cullinan's list of cases and dates of attack shows that this condition was satisfied, and more than satisfied, 16 cases of typhoid fever having occurred in the smaller number of uninoculated exposed to infection in the period subsequently to Nov. 5th, as against 14 cases in the larger number of uninoculated exposed in the earlier period. In conformity with this it may be confidently assumed that the comparison based on the average daily strength is a comparison which does not here exaggerate in favour of the inoculation procedure. The comparison in question is as follows:—

*Comparative Incidence of Typhoid Fever in Inoculated and Uninoculated calculated upon the Average Strength of the Respective Groups during the Period intervening between the Commencement of the Inoculations and the Termination of the Epidemic.*

—	Average strength.	Number of cases.	Number of deaths.	Percentage of cases.	Percentage of deaths.
Uninoculated	298	30 (- 1 f)	4	10·1	1·3
Inoculated ...	339	5 (+ 1 f)	1	1·5	0·3

It may be noted in conclusion that the result is in conformity with that of all the statistical returns of anti-typhoid inoculation which have reached me.

Netley.

## THE EFFECTS OF LEAD UPON LEAD-WORKERS IN THE STAFFORDSHIRE POTTERIES.

BY FRANK SHUFFLEBOTHAM, M.A., M.B., B.C. CANTAB.

WITH a view of determining to what extent the health of lead-workers in the Staffordshire potteries is affected by their employment I have made systematic examinations of the workers employed in 13 factories. These examinations have not been of selected cases, but include all the workpeople (with one exception) engaged in lead processes at the factories which I have visited, and my choice of these factories was made in the endeavour to obtain a series of potteries which might be regarded as a fair representation of the whole industry. Table I. gives the firms whose workpeople I have examined as well as their products of manufacture.

TABLE I.—*Showing the Names and Situations of the Firms and Products of Manufacture where the Persons examined were employed.*

No.	Name of firm.	Situation.	Products of manufacture.
1	Booths.	Tunstall.	Earthenware and tiles.
2	Doulton and Co.	Burslem.	Earthenware, china, and sanitary ware.
3	Dresden Porcelain Co.	Longton.	China.
4	T. Forester and Sons.	Longton (Phoenix and Mill Works).	Majolica and art pottery.
5			
6	W. H. Grindley and Co.	Tunstall.	Semi-porcelain.
7	Grove and Co.	Longton.	Earthenware.
8	Hawley, Webberley, and Co.	"	Earthenware and majolica.
9	Longton Porcelain Co.	"	China.
10	J. and G. Meakin	Hanley (Eagle and Eastwood Works).	Semi-porcelain and granite.
11			
12	Ridgways.	Shelton.	Earthenware and semi-porcelain.
13	Josiah Wedgwood and Sons	Etruria.	Earthenware, china, majolica, and tiles.

Between 6000 and 7000 people are employed at these manufactories, of whom 528 are engaged in lead processes. The figures here given show the approximate ratio of lead-workers to the total number of operatives throughout the whole of the Staffordshire potteries.

These lead processes involve many different occupations, the nature of which I will briefly explain. They may be divided into two main divisions, the first of which comprises the various operations of glazing, while under the second heading may be grouped certain decorative processes in which lead compounds are used for their colour effects. In the former group the work is subdivided between dippers, dipping-house assistants, ware-cleaners, and glost-placers. "The dipper's business is to coat the 'biscuit' ware with a layer of glaze by plunging it into a bath containing the finely-ground glazing materials in suspension in water" (Burton). Lead compounds are essential constituents in the preparation of glazes for every kind of pottery except hard porcelain and salt-glazed ware. The assistants in the dipping-house hand up the ware to the dipper and take it from him when it has been dipped, and the ware-cleaners "examine the pieces to see that they are properly dipped and remove all superfluous glaze by scraping with a knife or other suitable means." The glost-placer packs the glazed ware into saggars which he carries into the ovens where the glaze is melted on. Dippers and glost-placers are invariably adult males, dipping-house assistants are either boys or young women, while ware-cleaning is an occupation carried on generally by females, but in some factories youths are employed for this purpose. In the principal decorative processes which entail the use of lead women and girls are for the most part engaged. The majolica painter paints coloured glazes upon the ware, and the

cyprian worker puts on the different coloured glazes at the dipping-tub. Ground-layers, aerographers, and colour-dusters are operatives who use lead compounds in the form of dust, which is applied to the surface of the ware after it has been glazed and fired. The glazes and colours are prepared by millers and glaze- and colour-mixers, and the sagger-washer is generally a labourer who devotes several hours in each week to washing the interiors of the new saggars with a lead-containing glaze. Table II. shows the occupations of the people I have examined and also the time they have worked in lead.

It should be noted at the outset that lead poisoning is a very subtle disease, which may assume many different forms the symptoms of which are common to other diseases, and its diagnosis should only be made after the most careful examination. The disease is characterised by the following symptoms: (a) anæmia, (b) blue line on the gums, (c) biliousness, and (d) headache, apart from biliousness; while in more severe cases we may find (e) constipation, (f) gout, (g) colic, (h) paralysis of the arms and the legs, (i) epilepsy, (j) insanity, (k) disturbance of vision, (l) abortion, and (m) that group of symptoms pointing to chronic Bright's disease. None of these symptoms, however, are pathognomonic of lead poisoning. Anæmia is the commonest disease to which girls and young women are subject, whether they work in lead or not. Headache is one of those complaints of which everyone has had experience more or less; when accompanied by loss of appetite, nausea, and vomiting its cause may be traced to carious teeth, to improper food, or to alcoholism. Constipation may be due to 50 different causes: it is often a family complaint, or it may result from coarse food or sedentary habits. Again, lead is not the only cause of colic. Heredity is an important predisposing cause to gout, to chronic Bright's disease, and to abortion, and along with chronic alcoholism in the parent and syphilis is a potent factor in the production of epilepsy and insanity. In a patient suffering from lead poisoning the blue line on the gums often gives the clue to the nature of the complaint, but the blue line unaccompanied by any of the above symptoms is not lead poisoning. When any of these symptoms have arisen in the 527 cases which have come under my notice I have endeavoured to ascertain their true causes and have not immediately jumped to the conclusion that lead was the source of all the trouble. In Table III. will be seen some of the results of my examinations.

Not a single case of gout, epilepsy, insanity, or disturbance of vision (excepting cases of presbyopia) had ever occurred in any of the 527 workpeople since they began to work in lead. A youth and a woman had suffered from epilepsy as children, and 24 work-people had a strong family history of this disease; but in spite of the predisposing tendency of their employment superimposed upon an hereditary liability none

of them had been affected in any way. Near relations of 14 lead-workers have been confined in the county asylums for mental diseases. Again, we might expect to find that the hereditary tendency would be accentuated by their employment, but in no case was there any history or any sign of mental trouble in the lead-workers themselves. I have had

TABLE III.—Showing the Results of the Examinations.

No.	Symptoms.	Found in—	Remarks.	References to other Tables†
1	Anæmia.	6 women.	All were anæmic before they commenced to work in lead.	V.(a)
		19 men.	Caused for the most part (1) by excessive alcohol drinking, and (2) by carious teeth.	IV.(a)
2	Biliousness.	30 women.	Caused by (1) carious teeth, and (2) by excessive tea-drinking. One woman was suffering from lead-poisoning. (See paralysis and Table V.(a).)	V.(a)
		21 men.	Caused by (1) carious teeth, (2) heat of ovens, and (3) weight of saggars (a large number of men temporarily suffer from headache after drinking bouts).	—
3	Headache apart from biliousness.	35 women.	Caused by (1) constant use of hair-curlers, by (2) carious teeth, and by (3) heat of the workshops.	—
4	Constipation.	1 man. 19 women.	Much below the general average.	V.(b)
5	Colic.	1 woman. 4 men.*	Due to ovarian disease. At time of examination apparently enjoying good health.	V.(a) IV.(a) IV.(c)
6	Paralysis of arms.	1 woman.	A marked case of paralysis of both arms, accompanied by vomiting, nausea, headache, constipation, in addition to the blue line on the gums. She was a majolica paintress who had worked in this occupation for 12 years.	V.(a)
7	Initial symptoms of chronic Bright's disease.	7 men. 2 women.	Not a large number since 61 operatives had reached the age of 40 years. Three of the 7 men were brothers.	IV.(b)

\* In these cases there was a history of colic.

† The references in the last column will show which of the lead-workers included in the table have the blue line on the gums.

the opportunity of examining one man who was sent to Wolverhampton for electrical treatment, but after a careful examination and a quiet talk with him I was of the opinion that he had been suffering, and was suffering, from gonorrhoeal rheumatism.

*The blue line on the gums.*—I have already remarked that the blue line on the gums, when unaccompanied by other symptoms, does not denote lead-poisoning. It merely indicates the presence of lead in the system. This blue line is a series of black dots along the edge of the gum, and consists of a deposit of lead sulphide formed by the action of the sulphur found in the tartar of the teeth on the lead-containing organic compound held in solution in the blood. It may be quite marked and observable by the naked eye; in some cases it is very faint and only seen by the aid of a magnifying lens. In nine lead-workers I noticed a

general blueness of the gums, although no line was observed. There is one condition which may simulate a blue line. Several times I have seen between the edge of the gums and the teeth a deposit of soot (which in combination with common salt is frequently used as tooth powder) look at first sight very much like the blue line, but on using a lens the error has been detected. Tables IV. and V. give details of each lead-worker in whom the blue line or blueness of the gums was perceived.

*Abortion.*—It is a reputed fact that the wives of lead-workers are prone to abortion, but my own observations hardly confirm this. 188 of the men were married and the wives of 19 of them had had one miscarriage each, seven had had two miscarriages each, and four three miscarriages. The wives of the remaining 158 married men had had no miscarriages. In six cases the miscarriages took place before

† In this case the miscarriages took place before the mother commenced to work in lead.

the husband commenced to work in lead. Table VI. (a) gives statistics as to the number of pregnancies of the lead-workers' wives who have never aborted, from which it will be seen that these people are very fertile. Table VI. (b) offers similar information about the wives who have had miscarriages. A comparison between these tables shows that in Table VI. (b) not only is the average number of pregnancies greater than in Table VI. (a), but also the average number of normal confinements. Two of the men whose wives appear in Table VI. (b) are found in Table IV. (a) as showing a distinct blue line on the gums, but neither of these men could be said to be suffering from lead-poisoning. The majority of the miscarriages recorded in Table VI. (b) are most probably due to the frequency of the pregnancies.

Among the married female workers 18 had had miscarriages out of a total of 55; seven of these had miscarriages before they commenced to work in lead, and three other women had an hereditary tendency to abort. Many of the miscarriages are due to the fact that the women continue their work as usual during the time they are pregnant to within a day or two of confinement. Reference to Tables V. (a), V. (b), and V. (c), will show that four women who experienced miscarriages had the blue line on the gums, one of whom had

\* In these cases the miscarriage took place before the mothers commenced to work in lead.

*Final conclusions.*—After giving each case which has come

under my observation full consideration I have come to the following conclusions:—

1. That of the 527 lead-workers I only met with one case of lead-poisoning.

2. That individual symptoms, which at first sight might have been attributed to lead-poisoning, were found upon closer examination to be due to other causes.

3. That the health record of the lead-workers was excellent (the complaints I have mentioned are for the most part only minor ailments). Of 348 men 196 have not lost a single day's work through ill-health from any cause whatever since they commenced to work in lead, and the same may be said of 90 out of 124 single women; 26 out of 55 married women have only been absent through confinements.

4. That the general condition of the work-people was good and would compare favourably with that of a like number of workers in any average healthy trade.

5. That the 91 operatives who had worked in lead for over 20 years were not suffering any ill-effects from their employment, although they had worked for years under practically no regulations.

6. That it must always be remembered that lead-workers are subject to the common ailments of life just in the same way as other people.

Newcastle-under-Lyme.

## ACUTE DILATATION OF THE STOMACH, WITH ILLUSTRATIVE CASES.<sup>1</sup>

BY H. CAMPBELL THOMSON, M.D., M.R.C.P. LOND.,  
ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

ACUTE dilatation of the stomach is characterised by its sudden onset, by the vomiting of enormous quantities of fluid, and by very severe general symptoms, which in the recorded cases have always ended fatally within a few days after the first onset of the disease. The condition was first fully described by Dr. Hilton Fagge<sup>2</sup> who recorded four cases, two of which had come under his own personal observation. Since then a case has been recorded by Mr. Henry Morris,<sup>3</sup> but beyond these the subject does not appear to have attracted much attention. I have during the past three years made post-mortem examinations upon four cases in which death was immediately due to this condition, and I believe that the disease, though of course very uncommon, is not so rare as has generally been supposed, and that probably the difference between the very serious cases and the less severe forms of dilatation, also acute, which not infrequently accompanies severe illnesses, is one of degree rather than of kind. Before referring to the cases recorded by others I will give a brief account of those which have come under my own notice, and I must here acknowledge my indebtedness to Mr. Henry Morris and Dr. Kingston Fowler who have kindly allowed me to make use of the clinical notes of cases which have been under their care. The first case is one in which acute dilatation suddenly supervened upon chronic dilatation, the latter being due to a growth of the pylorus.

CASE 1.—The patient was a man, aged 48 years, who was admitted into the Middlesex Hospital on Oct. 31st, 1899, under the care of Dr. Kingston Fowler. Symptoms had existed for three months before admission, the chief being discomfort after food and frequent vomiting. On admission the patient was found to be considerably emaciated; the stomach was dilated and extended downwards to about an inch above the umbilicus; no splash was obtained. An indefinite tumour could be felt in the epigastrium. The pulse was 84, regular, and the patient, considering the disease he was suffering from, did not appear to be unduly ill, and certainly presented no immediate symptoms of an alarming character. On Nov. 3rd—i.e., three days after admission—the stomach was washed out in order to relieve the vomiting, which occurred at intervals and which in no way differed from that which usually takes place in cases of pyloric cancer. On this occasion 38 ounces were drawn off with a soft syphon tube. The patient expressed himself as feeling relieved by

<sup>1</sup> A paper read before the Royal Medical and Chirurgical Society on Oct. 22nd, 1901.

<sup>2</sup> Guy's Hospital Reports, 1872-73.

<sup>3</sup> Transactions of the Pathological Society of London, vol. xxxiv.

the washing, and the process was repeated on the following morning (the 4th), no vomiting having occurred in the interval. Relief was again obtained and the patient was able to take about half a pint of beef-tea and a very little pudding at mid-day. Suddenly, during the afternoon, a change for the worse took place, which was ushered in by slight hiccough, accompanied by abdominal pain and uneasiness, which the patient attributed to flatulence; at 6 P.M. the pain was considerable; at 8 P.M. he vomited about eight ounces of thick, dark brown fluid; and an hour later (9.15 P.M.) he was very collapsed, with a feeble pulse of 120, a subnormal temperature, and cold extremities. There was now severe abdominal pain, the outline of the stomach was easily seen, and appeared to cover a greater area than formerly; there was no muscular rigidity, but the abdominal walls did not appear to move with respiration. In the face of these acute symptoms it was thought possible that a perforation of the stomach might have taken place. A quarter of a grain of morphia was given hypodermically and hot bottles were put to the feet; no food was given by the mouth. About midnight the patient was very wakeful, but slept after a second injection of morphia. The next day (the 5th) the patient was drowsy but said he had no pain; the pulse was 120 and the abdomen moved slightly with respiration; the lower border of the stomach now reached the umbilicus and a tympanic percussion note could be obtained in the left axilla as high as the fourth rib. Nourishment was given by nutrient enemata and suppositories, which were retained. The general condition remained about the same all day, but towards evening he became more collapsed and at 6 P.M. a hypodermic injection of strychnine was given. The abdomen, however, became more distended. Death took place at 2.55 A.M. on the morning of the 7th. During the acute illness the urine had become very scanty, none at all was passed from 1 A.M. till midnight on the 5th, when a catheter was passed, but only one ounce was drawn off. At the post-mortem examination the contents of the abdomen were almost entirely obscured by the dilated stomach, which was tightly distended with gas and also contained a considerable quantity of dark brown fluid. In shape the stomach was cylindrical, the lesser curvature making a sharp curve, while the greater curvature was rounded and reached a point just below the level of the iliac crest. There was a growth of the pylorus which considerably narrowed the orifice.

This case, then, is an example of acute dilatation suddenly supervening upon a chronic one; owing to the stricture the stomach had, no doubt, for some time had a considerable strain put upon it, and then suddenly acute dilatation set in. Possibly the slight irritation produced by washing out the stomach may have upset the balance or, and what I think is more likely, the growth may have implicated some of the nervous structures in the neighbourhood.

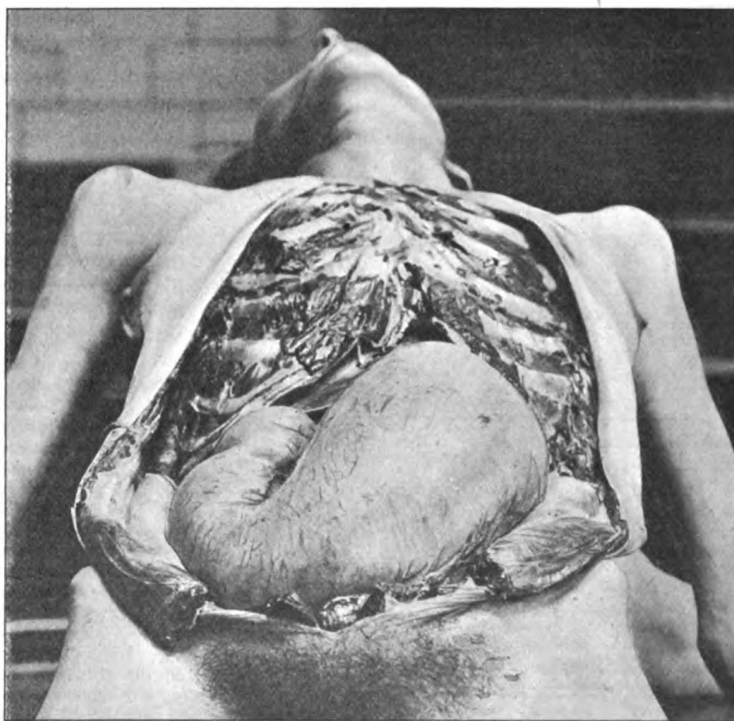

The second case occurred after an exploration of the kidney.

CASE 2.—The patient, a man, aged 26 years, was admitted under the care of Mr. Henry Morris with symptoms pointing to the presence of renal calculus, and on these grounds the right kidney was explored by a lumbar incision on July 30th, 1900; there was nothing of special note connected with the operation. Vomiting commenced a few hours after the operation was performed and persisted almost incessantly up to the time of death, which took place on the evening of August 4th. The temperature fluctuated a little but kept low, and reached 98° F. before death; the pulse was very rapid, varying from 120 to 140 per minute. There was no suppression of urine—on the day of death 33 ounces were passed. At the post-mortem examination, which was made on August 5th, I found the stomach to be enormously distended and of cylindrical shape, the lower end

being on a level with the iliac crest; the first part of the duodenum was also distended. The contents of the stomach consisted of gas and a considerable quantity of thick green fluid. The intestines, with the exception of the first part of the duodenum, were all somewhat collapsed. There was no obstruction of the pylorus and no definite change of any kind was to be observed in the stomach walls. The recent incision into the right kidney was in process of healing and all the structures around it appeared to be healthy; there was some chronic nephritis of both kidneys.

CASE 3.—The patient was a female, aged 40 years, who was admitted into the hospital under my care (in the absence of Dr. Fowler), suffering with deep jaundice, which had come on suddenly with severe pain a few weeks previously. As the diagnosis between gall-stones and malignant disease was somewhat uncertain it was thought advisable to explore the abdomen; this was accordingly done by Mr. J. Murray on April 30th, 1901, the condition proving to be a growth of the head of the pancreas and a distended gall-bladder; the gall-bladder was drained and the wound was sutured. All went perfectly well till May 4th, when the patient passed a restless night and vomited early in the morning of

FIG. 1.

Acute dilatation of the stomach complicating lobar pneumonia and pleurisy.

May 5th. She also became very collapsed, but this may have been partially due to some hæmorrhage which occurred in the wound. The vomiting, however, persisted and large quantities of brownish fluid were thrown up; the urine became scanty and the temperature was subnormal before death, which took place on the 9th. The post-mortem examination showed the stomach to be greatly distended, but chiefly with gas, there being only a small quantity of greenish fluid present. The stomach had the same cylindrical appearances as in the other cases, but was not quite so large as any of the other three which I have met with. There was a hard tumour of the head of the pancreas, but it was not very prominent, and as far as could be seen it had not caused any definite obstruction to the pylorus, nor was any obvious dilatation of the stomach noted when the abdomen was explored.

The next case is one in which acute dilatation occurred as a complication of pleurisy and pneumonia.

CASE 4.—The patient, a female, aged 24 years, was admitted into the hospital under the care of Dr. Fowler on June 26th, 1901. She was first taken ill on the 24th, and previously to that she had been in good health. On admission

there were signs of consolidation over the lower lobe of the right lung and also well-marked signs of pleurisy on the same side. The next morning (the 27th) there were some improvement and no signs of any extension of the disease; later in the day, however, there were pain and friction in the left side and at 1 P.M. the patient suddenly vomited. The vomiting continued incessantly from 1 P.M. on the 27th till 6.30 A.M. on the 28th, and then ceased till 1.5 P.M. the same day, when it re-commenced and continued till death, which took place at 2 A.M. on the 29th—i.e., about 36 hours after the vomiting first began. The vomit was of a dark greenish colour, and large quantities were brought up without any violent effort. The abdomen was very carefully examined on the 28th, but no distension was observed until 3 P.M. of that day. The urine was passed in usual quantities throughout the illness, but it may here be mentioned that at the post-mortem examination the bladder was perfectly empty. At the post-mortem examination the stomach was enormously distended and reached down to the pubes (*vide* Fig. 1). The stomach contained about 35 ounces of dark greenish fluid, and the mortuary attendant informed me that a large quantity had escaped by the mouth when the body was being removed. On relieving the stomach of its contents it rapidly shrank, and in a few minutes it had the appearance of being but little larger than normal, and no one seeing it would have thought that it could have been so enormously dilated only a few minutes before; the stomach walls appeared to be perfectly healthy. The intestines were collapsed, apparently from compression; there were no other abnormalities in any of the other abdominal organs except that the liver was rather larger than normal. In the thorax the lower lobe of the right lung was consolidated and in a condition of red hepatisation; there was no pneumonia elsewhere. Both pleurae were extensively covered with a thick yellow exudation, which on the left side was particularly marked over the base of the lung where it rested on the diaphragm.

some surgical operation, which may or may not be connected with the abdomen. In the case recorded by Mr. Morris, which has already been referred to, the operation consisted in the removal of some necrosed bone from the foot; the patient began to vomit about an hour after the conclusion of the operation and brought up quantities of thin, greenish fluid almost continuously until death took place two days afterwards. The accompanying table shows the associations which have been observed between acute dilatation of the stomach and other lesions and surgical operations.

From this table the cases may be conveniently arranged in the following groups: (1) those in which the dilatation occurred without any apparent cause, and in which, after death, no other lesion was found (Case 2 and Case 3); (2) those in which after death some other lesion has been found (Cases 1, 4, 7, 9, and 10); and (3) those in which the dilatation has followed some surgical operation and in which after death no other lesion has been found (Cases 5, 6, and 8). In two cases there was some surgical interference as well as another lesion found after death—viz., in Case 7, in which a tube was passed into the stomach, and in Case 9, in which the abdomen was explored; and although these operations may have had a certain amount of influence in determining the onset of the condition there can, I think, be little doubt that the predominant factor was the growth in each, which, as will be seen later, produced the effects by impinging surrounding nerve structures. I may here mention another case, of which Mr. Henry Morris has kindly given me the notes, where the dilatation followed an operation. The patient, a thin weakly man, underwent nephrectomy for polycystic disease of the kidney, after which all the symptoms of acute dilatation set in: the abdomen became unsymmetrically distended and great quantities of fluid were vomited until the time of death. Although there can be no doubt as to the nature of the disease, as no post-mortem examination was obtained I have not included it in the table.

TABLE OF CASES OF ACUTE DILATATION OF THE STOMACH.

Acute dilatation of the stomach may arise without any apparent cause whatever, the patient being, as far as one can tell, in ordinary health up to the time of the onset of acute symptoms. This was so in Dr. Fagge's second case, in which the patient died after three days' acute illness, and after death no other morbid condition was found except that of the stomach. Dr. Fagge considered that the actual process of enlargement of the stomach is more gradual and is in the end succeeded by sudden symptoms of great severity; but although this is sometimes the case—as, for instance, in the case I have recorded, where there was obstruction to the pylorus, and possibly also in the case in which there was a tumour of the pancreas—there is no reason whatever to believe that there was any slow dilatation previous to the acute symptoms in the other two cases.

In many cases (*vide* Table) some other morbid condition is found in addition to the dilated stomach, and in other instances the dilatation appears to follow immediately upon

There is yet another group of cases in which in debilitated subjects the ingestion of a large quantity of badly masticated food appears to have been the exciting cause. In a case mentioned by Dr. Walter Broadbent<sup>4</sup> a man, after tramping about the country for two days without food, and who was therefore very exhausted, partook of a large meal of roast pork, after which he was seized with abdominal pain and vomiting, which in spite of treatment terminated fatally in two days. After death the stomach was found to be enormously dilated, the lower border reaching nearly to the pubes. In a case recorded by Dr. W. H. Dickinson,<sup>5</sup> dilatation occurred in a child suffering from fatty degeneration of the heart, and after death the stomach, which was greatly distended, was inflated with gas and contained a large quantity of meat and potatoes, which were in lumps with sharp angles and edges, just as they had been cut by the nurse.

<sup>4</sup> Medical Magazine, July, 1901.

<sup>5</sup> Transactions of the Pathological Society of London, vol. xlii.

The following is a summary of the symptoms and post-mortem appearances:—

**Distension of the abdomen.**—As might be expected, the distended stomach gives rise to a swelling of the abdomen; the swelling is not uniform, but fills chiefly the left half and lower part of the abdomen, the right hypochondrium sometimes appearing to be flattened. This swelling, which is of diagnostic value, is not, however, quite constant, for in the case recorded by Mr. Morris it is stated that the abdomen was retracted, and after death, although the stomach was enormously dilated and occupied almost the whole of the abdomen, its anterior surface was said to be flattened. No doubt the abdominal swelling varies with the vomiting, especially in those cases where there is a large quantity of fluid in the stomach, as in one of Dr. Fagge's cases, where the swelling disappeared after a quantity of fluid had been removed by the stomach-pump. Peristaltic waves of contraction do not seem to have ever been observed in these cases, which, I think, rather opposes the theory suggested by Pepper and Stengel, that spasmodic contraction of the pylorus is the cause of the dilatation.

**Vomiting.**—Vomiting appears to be a constant symptom and usually large quantities of brownish or greenish fluid are brought up. The fluid is usually thin and watery and is generally vomited without causing the patient any great effort or distress.

**Urine.**—As a rule the urine becomes very scanty and almost entirely suppressed for the last 24 hours before death. In seven cases in which the condition of the urine is mentioned there was more or less suppression in five, and in three of these it was almost absolute during the last 24 hours of life; in two it is mentioned that a catheter was passed under the idea that there might be retention, but only a few drops of water were drawn off.

**General symptoms.**—The general symptoms are those of collapse; the pulse is small and very rapid, the respirations are frequent, and the temperature is low, usually subnormal. There is also great thirst, which is probably accounted for by the excessive vomiting of fluid.

**Condition of the stomach.**—The appearance of the stomach as seen after death is very characteristic; it is like a tightly distended cylinder, shaped like a V with one limb shorter than the other. The angle between the two limbs formed by the lesser curvature is a very sharp one (*vide* Fig. 2). The

FIG. 2.

Diagram of shape of stomach in acute dilatation.

walls of the stomach, though so much distended, do not after the stomach has collapsed appear to be much thinned, and, moreover, they retain their elasticity, as shown by the vomiting during life and by the contraction which occurs after death as soon as the contents are let out. There are, in fact, no definite abnormalities to be observed in connexion with the stomach walls.

**Condition of the intestines.**—The condition of the intestines varies. Usually they are collapsed and have the appearance of having been compressed by the distended stomach; sometimes parts of them may be distended, as in Dr. Fagge's first case, in which there was some distension of the cæcum and ascending colon.

The immediate cause of acute dilatation of the stomach

probably depends upon some disturbance of the nervous system which gives rise to paralysis of the muscular walls and which also frequently causes excessive secretion into the stomach cavity. The only other explanation which seems within the bounds of possibility is that the distension might be caused by a rapid production of gas within the stomach. This mode of origin was actually suggested in one case in which the patient was known to have drunk two bottles of effervescing lemonade not very long before the acute symptoms began; but Dr. Hughes Bennett, under whose care the case was, rejected the idea and preferred to leave the cause unexplained rather than to suppose that gas sufficient to distend the stomach so enormously could have been generated by two bottles of lemonade. Neither is there, as far as I can find, any evidence whatever that there has been any undue putrefaction taking place in the stomach in any of these cases and, moreover, this view of the causation would not explain the occurrence of excessive secretion.

In considering the part which the nervous system may take in the production of acute dilatation there are two processes to be taken into account—viz., (1) the dilatation and (2) the increased secretion, and the question at once arises concerning the relationship of these two processes to each other; do they take place independently or is one dependent in some way upon the other? The inclination hitherto seems to have been to look upon the increase of secretion as the primary condition and to regard the dilatation as secondary and immediately dependent upon it. This appears to have been the view taken by Dr. Fagge when, in speaking of his first case, he says that the stomach was paralysed from over-distension and unable to rid itself of its burden. Mr. Henry Morris also took this view; he considered that both dilatation and vomiting were due to excessive secretion, and on these grounds proposed that the disease should be called "acute gastrorrhœa." In support of this view Mr. Morris quoted Moreau's experiments which showed that after a loop of intestine had been isolated by ligatures, and all the nerves passing to it along the mesentery cut, a paralytic secretion took place, and the intestine was found to contain a quantity of fluid which on chemical examination proved to be a very dilute intestinal secretion. Dr. P. H. Pye-Smith and Sir T. Lauder Brunton<sup>6</sup> have shown that the regulating influence conveyed by the nerves divided in Moreau's experiments arises from some of the ganglia in the solar plexus. As a result of Mr. Morris's paper Dr. J. F. Goodhart<sup>7</sup> brought forward notes of all the cases of dilated stomach not due to pyloric obstruction observed in the post-mortem room of Guy's Hospital from 1875 to 1882, and in the light of general information obtained from these Dr. Goodhart concluded that "paralysis of the viscus is, if not the determining cause, at any rate an accompanying condition." It is, of course, naturally very difficult to establish the exact relationship between the two conditions, but although they are so often present together, and produced by the same underlying cause, I think that the available evidence shows that they are at any rate distinctly separate processes and that the dilatation is not the mere mechanical result of excessive secretion. In some cases, for instance, there is very little fluid present, the stomach being in such cases almost entirely blown out by gas.

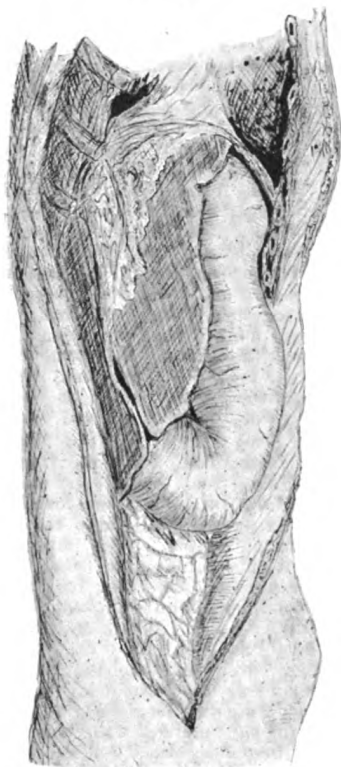

I have recently had an opportunity of observing a very interesting case in which the stomach appeared to be in an early stage of acute dilatation, and in this instance there was no fluid at all, and only a very slight trace of semi-solid, almost completely digested food. The patient was an old woman who died almost immediately after the conclusion of a severe operation upon the lower jaw, and at the post-mortem examination the stomach was distended with gas and had the cylindrical sausage-shaped appearance which is so typical in the more advanced cases. The appearance of the stomach in this case is seen in Fig. 3, which is taken from a sketch made at the time. The stomach, though much distended (it measured about nine inches in length in the longer limb and about seven inches at its greatest circumference), was nothing like the size which the others I have met with reached; but naturally there must be an early stage of the condition, and this case, I believe, is an example of such. This case, then, as far as it goes, tends to show that the distension may take place

<sup>6</sup> Reports of the British Association for the Advancement of Science, 1874 and 1875.

<sup>7</sup> Transactions of the Pathological Society of London, vol. xxxiv.

independently of the secretion, and some information regarding the relationship between the two processes may, I think, be obtained from the consideration of cases of chronic dilatation which depend upon pyloric obstruction. In many of these there is a very great secretion, just as there is in the acute cases. Osler and Macrae,<sup>8</sup> for instance, mention a case of dilatation of the stomach due to malignant growth of the pylorus in which on two occasions the stomach was

FIG. 3.

Appearance of a stomach which was apparently in an early stage of acute dilatation.

washed and emptied as thoroughly as possible, and for 48 hours afterwards the patient was fed by the rectum and all nourishment by the mouth was stopped. At the expiration of this time, on the first occasion 545 cubic centimetres of fluid were drawn off, and on the second occasion 500 cubic centimetres. In such cases as this the increased secretion is obviously secondary to the dilatation, as it also frequently is in cases of chronic dilatation which are not due to obstruction, and it seems therefore that the increased secretion is an accompaniment of, or a result of, the dilatation rather than a cause of it. The two conditions, there is little doubt, are independent processes which come into action separately or in combination, and it is most likely that their relative importance varies. There can be no doubt that excessive secretion, when present, adds greatly to the gravity of the situation, but there does not seem to be any clear proof that excessive secretion can act as the dilating force unless there is at the same time some paralysis of the stomach walls. The stomach derives its nerve-supply from the vagi and the splanchnic nerves; stimulation of the vagi gives rise to peristaltic movements, while stimulation of the splanchnic nerves brings the movements to a standstill. Sir Michael Foster,<sup>9</sup> in speaking of the nervous mechanism of the alimentary canal, says: "We may, therefore, speak of fibres inhibitory of peristaltic movements of the stomach and intestines as passing from the spinal cord through the splanchnic nerves and reaching those organs through the abdominal plexuses." With regard to the nervous mechanism of secretion Sir Michael Foster says: "It has been suggested that while impulses reaching the stomach

along the vagi excite secretion those reaching the stomach along the sympathetic nerves inhibit it; but this has not been satisfactorily proved."

Dilatation of the stomach can probably be produced by the local interference of nerves of the stomach<sup>10</sup> or it may arise after a shock affecting the general nervous system. Examples of the latter are seen in cases such as that recorded by Mr. Henry Morris, where the dilatation followed an operation upon the foot, while examples of local interference are shown where the disease has followed some lesion in the neighbourhood of the stomach, and it is interesting to note how in Case 9 of the preceding table the onset of the condition appeared to coincide with the spreading of an acute pleurisy to the base of the left lung, which must be in close relationship to the nervous system of the stomach.

As cases of acute dilatation have followed closely upon operations it is necessary to inquire into the possibility of the anæsthetic having some influence in their causation. Mr. Morris considered this question fully with regard to his case and came to the conclusion that the anæsthetic was not to blame, and examination of the other cases does not show any direct evidence that the condition can be traced to this cause; but it would seem quite possible that under certain conditions an anæsthetic might influence the dilatation through its widespread effects upon the nervous system.

Acute dilatation of the stomach though of course very much more rare, is probably closely allied in its causation and nature to the paralytic distension of intestines which frequently occurs after severe abdominal operations, and also in inflammatory conditions of the peritoneum. At present there seems no adequate explanation as to why the intestines should be distended in some cases and the stomach in others, though most likely this difference depends upon differences in reaction to stimulation of different nerve ganglia.

I think that acute dilatation of the stomach, to some extent, is not so rare as supposed, and that if looked for all degrees of severity may be found between the slighter forms of dilatation, such as, for instance, are not infrequently noted in acute specific fevers, and the most severe and rapidly fatal cases such as I have described to-night. Treatment of the recorded cases seems to have been of no avail in checking the disease. The most obvious indication in these very severe cases is to relieve the distension of the stomach by means of a tube, but unfortunately, so far, this does not seem to have been followed by any permanent improvement, although it must be said that with the exception of one of Dr. Fagge's cases, in which temporary relief was produced, this mode of treatment does not seem to have received any extensive trial. All nutrition should be administered by the rectum, and the tendency to collapse met by hypodermic injections of strychnine. Some of the more serious symptoms are probably produced by the loss of the large quantities of fluid which are secreted, and this loss should be counteracted by injection of saline solution into the rectum or by transfusion. Lastly, it must be remembered that possibly on some occasions the condition may be a more general one than seems at first sight and that the dilatation of the stomach may be one of the local manifestations of general collapse.

## THE ACUTE RETRO-PHARYNGEAL ABSCESS OF INFANTS.

By S. VERE PEARSON, B.A., M.B., B.C. CANTAB.

THE acute post-pharyngeal abscess of infants is not a common complaint, but it is none the less important. This importance lies in the fact that if undiagnosed the case most frequently ends fatally. I have met with two cases of this disease in which tracheotomy was performed for supposed laryngeal diphtheria, one of which proved fatal; in the other, afterwards correctly diagnosed, the patient recovered. I can

<sup>10</sup> Paralysis of the muscular coat of the stomach limited to the pyloric portion, and preventing the propulsion of food into the duodenum, has been stated to be a cause of dilatation, and Dr. Wilson Fox ("Diseases of the Stomach," p. 215) quotes a case recorded by Andral where there was extensive ulceration of the pyloric region without obstruction and yet extreme dilatation of the stomach. Traube attributes such dilatation to destruction of the branches of the pneumogastric nerve.

<sup>8</sup> Cancer of the Stomach, p. 81.

<sup>9</sup> Text-book of Physiology, Part II., p. 491.

relate two more fatal cases, both of which were admitted into hospital with, and died from, broncho-pneumonia secondary to an undiagnosed post-pharyngeal abscess which had broken down. In one case the condition was recognised before death, but the patient was already extremely ill and the post-pharyngeal tissues had sloughed. In the other case, which occurred at the earliest period of infancy at which I have known suffering from this complaint to be experienced—namely, seven weeks—the abscess was not discovered until the necropsy revealed it. Irving Snow,<sup>1</sup> who recently published three cases, makes a similar statement—viz., that retro-pharyngeal abscess unrecognised and untreated usually ends in death. And Blackader<sup>2</sup> says that the notable fact with which one is impressed on reviewing the literature is the frequency with which these cases remain undiagnosed or receive faulty diagnoses. Yet the diagnosis is not as a rule difficult. The disease is frequently overlooked because its occurrence is not thought of. When diagnosed the prognosis is fairly good. For these reasons, then, I feel that this article, dealing with a few of the striking features of some cases which came under my personal observation during 1900, together with one or two details of some additional cases treated at the Shadwell Children's Hospital during the year 1899, may not be without interest, and possibly, I hope, not without some practical result in leading to a less frequent oversight of a disease which, although admittedly not common, is not, I believe, so rare as is generally thought.

The text-books on the diseases of children briefly describe the symptoms likely to occur; hence it will be unnecessary to enunciate them fully. I will lay stress upon those of practical importance only. The common type of case presents the following picture. An infant under two years of age is brought, the complaint being that during the course of the last few days the child's voice has become gradually muffled, that there has been difficulty in sucking, or apparent pain on swallowing, that the child has been restless, has loss of appetite, and has been constitutionally ill. In addition to this it is remarkable in my experience how frequently these troubles have been preceded, or are actually accompanied, by a purulent nasal discharge. Very often at the time that the infant is first seen there is considerable obstruction to respiration, sometimes accompanied by much recession. Such a case may easily be mistaken for laryngeal diphtheria, especially when it is found that some glands in the neck are tender and enlarged, and upon examination of the throat the tonsils appear red and inflamed and possibly covered with a mucoid secretion. But it will be observed that the voice is different from that in acute laryngitis, and there is not that characteristic croupy cough so often present with laryngitis. Also on more careful examination it will be noticed that one side of the neck is fuller than the other, and when looking at the throat it may be noticed that one tonsil and the corresponding posterior pharyngeal wall may appear to be pushed slightly forwards. I say this may be noticed, for it is by no means generally easy to make sure of it in an infant's throat, always rather difficult to examine. But there is an easy method for certainly diagnosing this condition, and that is by digital palpation of the post-pharyngeal region. Too much stress cannot be laid upon the importance of making a digital examination in all cases where symptoms suggest such a condition. A very small amount of education is required in order to detect a small swelling and the most inexperienced can diagnose a well-marked abscess in this region. The only difficulty which arises is the difficulty of making sure that the swelling has true fluctuation. In one of my cases the swelling was fairly big and quite elastic to the feel, but subsequent events proved that it did not contain pus. It is said to be very rare for the swelling to become at all large without suppuration having occurred, and this has certainly been my experience.

There is no point with regard to etiology upon which I wish to lay any stress. It seems to be generally admitted now that the cause of the abscess is acute post-pharyngeal suppurative adenitis. The frequency of an associated nasal discharge is of interest in this connexion. I regret to say that I was unable to carry out bacteriological examinations in the cases which came under my care. In one case, however, I had a cultivation made from the nasal discharge and Klebs-Löffler bacilli were found. And in another case, referred to below, pus evacuated from the abscess underwent a bacteriological examination, the report of which was

that "very plentiful chains of streptococci" were found. The cases with which this article deals are, of course, quite distinct clinically as well as etiologically from the chronic retro-pharyngeal abscess associated with spinal caries.

I now come to a very important part of the subject—namely, treatment. If the constitutional symptoms are slight and the swelling is small an expectant line of treatment should be followed. Under these circumstances the swelling may soon disappear, any local condition such as rhinitis having been attended to and a mild purge given. In all other cases, however, operative measures are indicated. Except in the worst cases immediate operation is not necessary. Very often an infant will be in a much better condition for operation by waiting for a short time, during which the swelling can be re-examined to see whether there is any chance of its being non-suppurative and subsiding. The only danger associated with this postponement is the possibility of an increase in the dyspnoea. Infants are liable to a sudden increase of any obstructive dyspnoea, and probably this is due to some spasm added to the primary cause. But my experience has been that not only is the constitutional condition of the patient better, but also the dyspnoea has become less marked, after about 24 hours' treatment; and this treatment should consist in the administration of a purgative and perhaps a simple saline mixture, careful feeding, together with a few small doses of brandy. If the dyspnoea is marked, and in any case, a steam kettle with a curtain over the head of the cot (not a steam tent) is useful, and a drop or two of antimonial wine added to the saline mixture often has the effect of counteracting the spasmodic element of the dyspnoea and easing the respirations.

Now as to the method of operating. I strongly advocate opening the abscess from behind the sterno-mastoid by Hilton's method. In an infant whose condition is already unhealthy it is extremely undesirable for him to swallow daily a certain amount of pus. It is impossible to teach an infant not to do this. And after operating through the mouth, however careful one is in irrigating the mouth and pharynx, it is impossible to prevent the swallowing of some of the purulent discharge which must persist for at least a few days. At the time of the operation it is of course possible by careful attention to the patient's position to prevent the pus from entering the trachea, when the abscess is opened through the mouth. This is a very real danger, considering the readiness with which a broncho-pneumonia is set up in such a patient, and it constitutes a very grave objection to that method of operating. And another objection is that these patients are always rather difficult to treat from the anaesthetist's point of view. It is undesirable in the case of either method to do without an anaesthetic, and the difficulties, and more particularly the dangers, are much increased, in my opinion, when the abscess is opened by the internal method—i.e., through the mouth. The actual operation in the case of opening the abscess externally is often quite easy and is generally not very difficult. Moreover, it seems to me that the after-treatment of cases treated by the external method is entirely satisfactory.

Now with regard to the operation itself there are one or two manipulative details to which I will call attention. The position of the incision should be immediately behind, and parallel to, the sterno-mastoid; its centre should be as nearly as possible on the same level as the centre of the swelling behind the pharynx, or a little below this. Towards the bottom of the wound the spinal accessory nerve must be avoided. Having used a knife to cut through skin and fascia, the posterior edge of the sterno-mastoid being carefully exposed and the muscle pulled slightly forwards, the knife should be abandoned in favour of a blunt dissector and a pair of dissecting forceps. By the time this stage of the operation has been reached it may have been necessary to remove one or two slightly enlarged glands situated behind the sterno-mastoid. From this time onward the operation consists in a careful separation of the structures until the prevertebral region is reached. The landmarks are the transverse processes and the plane of the anterior surface of the vertebral bodies. Keep well back, feel with the finger for these landmarks, and there will then be no danger of injuring the jugular vein or cervical sympathetic, the only two structures likely to be interfered with. The patient should never be at all deeply under, but at this stage of the operation he should be allowed to come round partially. Then matters are much facilitated by introducing one finger into the mouth and a finger of

<sup>1</sup> Archives of Pediatrics, January, 1901.

<sup>2</sup> Ibid., 1889, p. 80.

the other hand into the wound. By this means the exact limits of the abscess cavity can be made out. Then a fairly fine-pointed blunt dissector or similar instrument can be passed along the front of the finger in the wound and the abscess sac pierced. The pus flows out readily when the opening is made larger by means of a pair of sinus forceps guided into the cavity by the instrument already introduced. It is important to remember that the finger of one hand has been introduced into the mouth, and this should not touch the wound until it has been re-sterilised. Irrigate the cavity once or twice with some antiseptic solution. Then a very small drainage-tube should be introduced right to the greatest depth of the wound and perhaps a small strip of gauze around this superficially. One or two stitches are then put in to bring the edges together above and below the tube and an ordinary antiseptic dressing is applied. With regard to after-treatment there is nothing very much of importance. I have found it best to leave the small drainage-tube in for about 48 hours or three days, to irrigate the wound by gently syringing it with 1 in 4000 perchloride or biniodide solution for the first few days and after that with a weak solution of iodine. It is best to dress it twice within the first 24 hours of the operation, but after that once daily is sufficient. After the tube has been removed a very thin plug of gauze should be introduced and every other day slightly shortened. Some discretion is required in carrying out this detail; the point is to strike a mean result between getting a re-accumulation of pus and a long-lasting callous sinus. In my experience the latter error is by far the commoner. Some indication as to the rate of healing of the sinus is given by stating that in about three weeks from the time of the operation the wound should be healed. I feel sure that a rigorous attention to the details of antiseptics is one of the great aids in doing away with the formation of a callous discharging sinus.

In the following cases points illustrative of any peculiar difficulties which may arise will be emphasised. Otherwise only the briefest details of each case will be given.

CASE 1.—The patient was a male, aged four months; he had an abscess on the left side. Besides presenting most of the usual symptoms, including a purulent nasal discharge, he had considerable head retraction on admission and was very much cyanosed. The operation in this case was a very simple one, as the abscess was a large one and was found inclined to point not far beneath the surface just behind the sterno-mastoid. Recovery was the result, the wound being perfectly healed on the twentieth day.

CASE 2.—The patient was a female, aged six months; she had an abscess on the left side. Nasal discharge was present. The onset appears to have been somewhat gradual, it being stated by the mother that the patient had been ill for nearly a month. The chief complaint was that the infant had been liable to alarming fits of coughing with blueness. External operation was performed. Recovery ensued, the wound being quite healed on the fifteenth day.

CASE 3.—The patient was a male, aged two years; he had an abscess on the right side. He had been ill for a fortnight before admission. Nasal discharge was present, very profuse and purulent. External operation was performed. Recovery ensued, the wound being healed on the twenty-eighth day.

CASE 4.—The patient was a male, aged six months; he had a swelling on the left side. Nasal discharge was present. A few adenoid vegetations were also present. The small swelling disappeared without surgical treatment within a week.

CASE 5.—The patient was a male, aged 10 months; he had a swelling on the right side. In this patient Klebs-Löffler bacilli were cultivated from the purulent nasal discharge. There was rather more marked cervical adenitis present than in many of the cases. The expectant line of treatment was followed for three days, at the end of which time the swelling had become much larger and more elastic. But at the operation no pus was found. The operation was somewhat difficult for several reasons. The patient took the anæsthetic very badly and at one time suddenly stopped breathing and artificial respiration had to be performed. Also it was difficult to make sure whether or not a somewhat tense wall of the supposed abscess cavity had been pierced or whether the probe, the point of which could easily be felt by a finger in the mouth under the mucous membrane at the back of the pharynx, was tracking in the tissues immediately outside the capsule. In the end a sharp-pointed probe had to be used to make certain of this. This is the only case in

which a sharp instrument was used. The temperature in this case, which in nearly all cases is considerably raised for a short time, ran a very irregular course, at times becoming very high (e.g., 106° F.). The child very soon afterwards developed broncho-pneumonia and died five days after the operation. During this time the swelling became considerably smaller. Throughout the patient took food so badly that he had sometimes to be fed by means of a nasal tube. At the post-mortem examination the diagnosis was confirmed, a small swelling was found behind the pharynx, but no pus, and extensive broncho-pneumonia. The case was acute; the onset was rapid, the history of illness and nasal discharge only dating from three days before admission. It seems probable that the whole disease, retro-pharyngeal adenitis and broncho-pneumonia, was secondary to an acute diphtheritic rhinitis.

CASE 6.—The patient was a male, aged 11 months; he had an abscess on the left side. There was no nasal discharge. External operation was performed. The patient was discharged cured, with the wound firmly healed, on the nineteenth day.

CASE 7.—The patient was a male, aged seven months; he had an abscess on the left side. Nasal discharge was present. External operation was performed by the house surgeon who preceded me at Shadwell. In this case the internal jugular vein was wounded and this necessitated ligaturing above and below. At the end of five weeks the patient was discharged constitutionally fit, but still with a small discharging sinus. This healed satisfactorily before very long, the child being watched as an out-patient.

CASE 8.—The patient was a female, aged 11 months; she had an abscess on the left side. There was no nasal discharge. External operation was performed; recovery ensued. This patient was operated on by the house surgeon who preceded me towards the end of February. She also left the hospital with a small discharging sinus, and at the end of May I had a note with regard to her case that the small sinus was still discharging and rather deep. I was about to make arrangements for the re-admission of the patient with a view to scraping the sinus, but somehow I lost sight of her. She disappeared from the out-patient department and so I presume the sinus must eventually have healed.

CASE 9.—The patient was a male, aged eight months; he had an abscess on the right side, but encroaching much towards the opposite side. Nasal discharge was present. This patient was originally admitted for laryngeal diphtheria. I had to perform tracheotomy on the night of admission. He was an extremely weak and wasted child and it seemed quite improbable that he would recover from the diphtheria. He did, however, but unfortunately he was one of those cases in which there is extreme difficulty in leaving out the tracheotomy tube. He was in the hospital for many weeks, during which time he was on several occasions on the point of death from spasmodic dyspnoea. Eventually he developed a nasal discharge and post-pharyngeal abscess in addition to his other troubles. This abscess was opened by the resident medical officer by the internal method. The patient recovered from this complication. In the end, however, he died from a dyspnoic spasm added to his marasmic condition.

The four undiagnosed cases referred to at the beginning of this article presented no further points of particular interest beyond those already mentioned. I will now add brief notes of eight more cases. These did not, like the preceding ones, come under my personal observation, but are cases treated at the Shadwell Children's Hospital during the year 1899.

CASE 1.—The patient was a male, aged seven months; he had a swelling on the right side. No note is made with regard to nasal discharge in this nor in several of the following cases; but presumably where none is mentioned no discharge was present. This was a weakly patient who had been ill for two months. For a short time previously to admission he had been refusing food. On admission there were swollen glands in the neck and a swelling in the right post-pharyngeal region. This subsided without operative treatment and the patient was shortly afterwards discharged cured.

CASE 2.—The patient was a male, aged one year; he had a swelling on the right side. He had been ill for 10 days; there had been a nasal discharge for one week. On admission the chief complaint made by the mother was swelling of the neck and difficulty in swallowing. The external operation was performed and a satisfactory recovery ensued.

CASE 3.—The patient was a male, aged three years; he had a swelling on the left side. This is the oldest patient of the series, none of the others being over two years old. The case also presented a more chronic form than is usual. Possibly it was of a tuberculous nature. The onset was gradual during 10 weeks. The child was well nourished. There was no rise of temperature. There were swelling, dyspnoea with recession, and stridor. The external operation was performed. A large collection of pus was found. The patient was discharged cured on the fourteenth day after admission.

CASE 4.—The patient was a female, aged one year; she had a swelling on the left side. She was very ill on admission. She had a very irregular and high temperature. Some broncho-pneumonia was diagnosed. External operation was performed but no pus was obtained. A few days later the patient died. At the post-mortem examination purulent meningitis, pulmonary collapse, and a sloughing post-pharyngeal wall were found.

CASE 5.—The patient was a male, aged two years; he had an abscess on the left side, the onset extending over two weeks. Difficulty in swallowing solids and some difficulty in breathing were complained of. The patient was a well-nourished child. External operation was performed. Recovery ensued and the patient was discharged to the convalescent home on the eighteenth day having only a superficial wound. The temperature in this case was never above 100° F.

CASE 6.—The patient was a female, aged 14 months; she had an abscess on the right side. She had had swelling of the neck for 10 days and dyspnoea for one week previously to admission. External operation was performed. The patient was discharged cured on the twenty-eighth day.

CASE 7.—The patient was a male, aged seven months. In this case there was also some suppurative adenitis of the cervical glands, so that at the operation (the external method was used) two distinct cavities were opened. The one behind the pharynx was, so far as could be made out, unconnected with that in the neck. The patient died the same night, the temperature rising just before death to 109° F. At the post-mortem examination broncho-pneumonia was found.

CASE 8.—The patient was a male, aged seven months; he had an abscess on the left side. Swelling and difficulty in breathing were present for four days previously to admission. He was a well-nourished child. External operation was performed. The pus contained "very plentiful chains of streptococci." Satisfactory recovery ensued. In this case a few days after the operation it was noticed that there was slight narrowing of the left palpebral fissure with contraction of the left pupil. The pupils reacted to light. This condition passed off in about a week.

I am greatly indebted to Mr. R. W. Parker and Mr. L. A. Dunn, surgeons to the East London Children's Hospital, for their kindness in allowing me to make use of those of their cases which came under my own observation and treatment during my term of office as house surgeon to the hospital, and also for leave to abstract a few details from the notes of some cases which were treated at the hospital in 1899.

Brompton Hospital for Consumption, London, S.W.

## A CASE OF COMPOUND FRACTURE OF BOTH JAWS.

By H. WEIGHTON, M.B., C.M. EDIN.

IN June last a young man in descending a steep hill on a bicycle without an efficient brake lost control of the machine, and being unable to round the turn of the road at the foot of the hill was thrown with great force against a stone pillar. He was found at once by a passer-by and was removed to his home, luckily no great distance from the scene of the accident. On examination shortly afterwards the lower part of his face was found to be much swollen but it presented no external wound. There was a complete fracture of the lower jaw near the symphysis and also a detachment of a part of the alveolus in front containing three teeth. There was likewise a fracture of the upper jaw at each side in the region of the canine teeth, but with little displacement or deformity. The whole premaxilla could be

easily moved about. He suffered also from slight concussion which, however, passed off in a few hours. The fractures were treated temporarily by means of wire between the teeth on each side, the whole being fixed with an external poroplastic splint fitted to the chin and a four-tailed bandage. Next day I procured the assistance of Mr. H. P. Friend, surgeon dentist, who took a mould of both upper and lower dental margins and constructed an inter-dental gutta-percha splint. A hole was made near the centre of this, through which the patient could be fed. This after manufacture was found to fit very exactly, and the teeth were fixed in the sockets of the splints by means of a lining of soft gutta-percha. The poroplastic cap was reapplied to the chin and fixed in was position by means of a piece of elastic bandage carried over the head. The patient was fed on milk, beef-tea, &c., through a piece of tubing, and the whole mouth was rinsed out very frequently with dilute Condy's Fluid. With a little practice the patient was able to drink out of a cup or tumbler in the ordinary way without much difficulty. After five weeks' time the splint was removed and the fractures were found to be firmly united, with the exception of the fractured alveolar margin of the lower jaw, which ultimately became a sequestrum and had to be removed. The patient is now able to take ordinary food and there is no outward deformity.

Incidentally the patient brought to my notice soon after the removal of the splint the fact that in swallowing liquids a small quantity always regurgitated through the nose. This on examination was found to take place from a small fissure running antero-posteriorly in nearly the centre and near the posterior edge of the hard palate. It is about half an inch long and in width it just admits the ordinary surgical probe. How this complication has arisen it is somewhat difficult to imagine, and it is rather curious that it should make itself manifest just five weeks after the accident. It is almost certain that no foreign body could have penetrated the roof of the mouth at the time of the accident. A probable explanation may be found in the fact that a fracture of the hard palate had occurred which for some reason had not united at this spot, thus leaving a fissure in the bone. It is then possible that the soft structures over the fissure would become split during the healing process of the bone, and a complete communication between the mouth and nose become established.

Barnard Castle.

## Clinical Notes:

### MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

#### A CASE OF URTICARIA FOLLOWING IMMEDIATELY ON WASP-STING.

By T. WILSON PARRY, M.A., M.B. CANTAB., &c.

IN the late afternoon of Sept. 4th, 1901, I was summoned urgently to the case of a boy, aged 15 years, who had been stung by a wasp, and, my messenger added, "it was flying all over him." Being accustomed to eccentric messages from excited villagers who are anxious about their sickly friends I paid little heed to the nature of the message, though, of course, going at once to see the patient. I found him lying in bed with a red face, swollen lips, and much swelling, too, below the eyes. He was scratching himself with great vehemence and an examination of his trunk, arms, and legs revealed as typical an urticaria as one could ever wish to see. The history of the case was as follows. He had just finished his tea and was washing his hands when a wasp, which was in a somewhat lethargic condition, dropped into his basin and stung him on the ring finger of the left hand. Before he had finished his ablutions he was obliged to run to the closet so that he might be able to scratch himself to his heart's content, as he told me his whole body was in a terribly irritable condition. While examining him he complained of sickness and immediately vomited the contents of his tea. His temperature was 96.8° F. and his urine, which he passed about two hours after, was loaded with phosphates and contained also a trace of albumin. I gave him a simple mixture of salicylate of soda, carbonate of

soda, and bismuth, and the following morning the rash had entirely disappeared and, with the exception of the swollen finger that had been stung, he felt himself ready for his work again.

Two points of interest seem to attach themselves to this case. Firstly, from both personal observation and also from reference to the literature on the subject it would appear that general eruptions are exceedingly rare after wasp-stings; and secondly, the suddenness of the onset of the rash after the sting had been inflicted is also peculiar and seems to be indicative of a hypodermic injection of some toxic substance which might have been imparted with the sting. May it not be within the range of probability that there is in existence an urticaria-producing bacillus which may take its place among those myriads of bacilli which, though at present "undiscovered," are markedly suspected of being the causation of certain so-called "idiopathic" affections?

Youghreave, Derbyshire.

#### A CASE OF TOBACCO-POISONING IN A CHILD.

By JOHN HAWKES, M.D. ST. AND.

ON Sept. 4th, about 6 P.M., a child was brought to my house by her father and mother who stated that she had just taken a "deadly poison" but of the nature or description of the poison they could tell me nothing. She was two years old, of good physique, and was well nourished. Her face was flushed, her body was very warm, and her pupils were dilated to about twice their natural size. She was unconscious and entirely free from pain; her limbs were flaccid and her pulse was small and weak. Her parents, intelligent persons, were profoundly agitated. I at once administered an emetic of one drachm of ipecacuanha wine in half an ounce of water and despatched the father to procure the vessel containing the poison which she had taken, following up the emetic with small draughts of warm water, which procured emesis in about 10 minutes, the quantity of fluid vomited being about a teacupful and consisting apparently of tea. The man meanwhile returned with a half-gallon tin labeled "Poison" and containing a strong decoction of tobacco which he used in his business as a horticulturist. He also brought a pannikin of a dark viscid fluid of the consistence of treacle into which the child had dipped her fingers and then placed them in her mouth. She was still unconscious and had passed a liquid motion. I accompanied her home and in about an hour the pupils regained their normal size and the warmth of the body and the flushing of the face had sensibly diminished. I then administered a few drops of brandy diluted with water, having previously given some warm milk which she retained. About this time she faintly recognised her mother and recovered slight consciousness; in another hour she was rather more improved and was apparently sleeping when I left her, with instructions for the milk to be continued through the night and a little brandy to be given if any signs of coldness or collapse ensued. She passed a tranquil night and on the next morning I was gratified to find her completely recovered and playing about in her usual health.

Tobacco poisoning, though not rare in adults, is, I believe, very unusual in so young a child. Its first action, according to Sir Benjamin Brodie, is on the heart; secondarily, it causes convulsions and insensibility of the pupil. These were absent, but the mother noticed that in shifting the child the little one was quite limp. Probably the quantity taken was not sufficient to cause any more serious symptoms.

Shanklin, Isle of Wight.

**CARDIFF INFIRMARY.**—The new women's ward at the Cardiff Infirmary was opened on Oct. 15th. The ward contains 16 beds and it is estimated that the cost of maintenance will be £800 per annum. The necessary funds have been contributed by the ladies of Glamorganshire.

**LLANDRINDOD WELLS.**—The resident population of Llandrindod Wells has been doubled in the last 10 years and at the last census included 1828 persons. The medical officer of health (Dr. S. G. Floyd) reported to the district council on Oct. 11th that it was nearly six months since a resident had died and that there was a complete absence of infectious disease in the district.

##### A CASE OF PERFORATED GASTRIC ULCER; OPERATION; RECOVERY.

(Under the care of Dr. HUMPHRY J. WHEELER.)

IN the following case of successful suture of a perforated gastric ulcer about 26 hours had elapsed between the perforation and the operation, so that the recovery is more noteworthy. The empty condition of the stomach at the time of rupture was favourable. Another element in the prognosis frequently does not receive sufficient attention: this is the variety of microbic infection of the peritoneum which has occurred. It would be well if in all cases of operation for perforated gastric ulcer a bacteriological examination of the peritoneal contents were made. The question of the value of absence of the liver dulness in the diagnosis of perforation of the stomach or intestine is important. Stress was first laid on this point by Flint, and many others have subsequently insisted on its importance. Yet it is very doubtful if it is of any real value. Liver dulness may be present and yet perforation may have occurred, as in the case recorded below, and, on the other hand, the liver dulness may be absent although there has been no perforation. When other signs point markedly towards perforation absence of the liver dulness will serve to confirm this opinion, but if the other signs are indefinite it is well to place no reliance on the dulness over the liver.

A domestic servant, aged 19 years, was admitted into the High Wycombe and Earl of Beaconsfield Memorial Hospital at 4.30 P.M. on July 31st, 1901. The patient's father was living and in good health; her mother died from cancer. The patient had two brothers who were strong and well and one sister who suffered from spinal disease. The patient herself had been delicate since childhood and had suffered for a year from anæmia and dyspepsia for which she had been under treatment for five months, her symptoms being epigastric pain and tenderness, aggravated by food, occasional attacks of vomiting, constipation, and amenorrhœa. She had no hæmatemesis, but she had noticed that her stools were sometimes very dark, "like ink." On July 27th the epigastric pain was worse; she saw her medical man who prescribed for her, but she obtained no relief. On the 30th she had a meal at 4 P.M. consisting of tea, bread-and-butter, and currant bun. At 7.30 P.M. she was hanging some clothes on a line when she was suddenly seized with acute pain to the left of the umbilicus which radiated through to the back and upwards to the epigastrium. Dr. Wheeler saw her at 8.30 P.M. and found her doubled up with pain. Her pulse was weak and 84, the tongue was clean, and the temperature was 99° F. Her abdomen was tender all over, especially at the epigastrium, and was tympanitic. The liver dulness was not diminished. Her bowels had acted imperfectly on the 27th. There was no vomiting. She had been given whisky-and-water and brandy-and-water which increased the pain.

The patient's appearance suggested perforation, but Dr. Wheeler did not consider the symptoms conclusive in view of the normal area of liver dulness. He prescribed 10 minims of liquor morphiæ, two minims of dilute hydrocyanic acid, and five grains of bicarbonate of sodium to be given every four hours. He saw her the next morning at 10.30 A.M. She had passed a very bad night; the abdominal pain was excruciating and was aggravated by some spoonfuls of milk-and-soda which she had taken during the night and by a dose of castor oil administered by her step-mother in the morning. The abdomen was rigid, tympanitic, and very tender all over. The pulse was 126 and the temperature was 102°. The tongue was somewhat coated. Perforation

was diagnosed and her speedy removal to hospital was advised. A quarter of a grain of morphia was administered hypodermically and was repeated at 3.30 P.M. just before her removal. The journey of three miles to hospital gave rise to great pain and some collapse which caused a delay in performing the operation. A simple enema was administered which acted. At 9.30 P.M. the patient was placed under chloroform by Mr. J. G. Cort, which she took well.

An incision was made in the median line from one inch below the tip of the ensiform cartilage to one inch above the umbilicus. On opening the peritoneum it was seen to be inflamed. The stomach, which was very much distended, bulged forward and was seen by transmitted light to be empty. The transverse colon and omentum also protruded from the lower angle of the wound and gave rise to some difficulty. The peritoneal cavity was moderately full of semi-opaque fluid, but no gas or foreign material was detected. The exposed anterior surface of the stomach was carefully searched but nothing was found. On raising up the liver it was found that the under surface of the left lobe was adherent to the stomach by recently effused lymph; the adhesions were easily separated and the adherent portion of the wall of the stomach was seen to be puckered and thickened, but no perforation was seen. On passing a probe down one of the sulci it passed into the organ but no gas escaped. The stomach was carefully searched in all directions but no further signs of perforation were discovered. The edges of the puckered portion were then brought together with fine silk Lembert sutures which held well. The peritoneal cavity was carefully sponged dry and all visible lymph was removed, and the colon, omentum, and stomach were returned with some difficulty on account of their distension. A drain of iodoform gauze was inserted under the liver and was brought out at the middle of the incision. The peritoneum was next sutured with fine catgut; the abdominal walls were then brought together with deep and superficial silk sutures. The wound was dressed with sublimate gauze and wood-wool, which were kept in place by a many-tailed flannel bandage. The patient had a good pulse throughout and stood the operation, which lasted about an hour, very well. On recovering from the effects of the anæsthetic at 1 A.M. she retched a little and complained of pain. A quarter of a grain of morphia was injected and she was given a nutrient enema of beef-tea and brandy. She passed urine naturally. The nutrient enemata were repeated at 4 and 10 A.M., and another hypodermic injection of a quarter of a grain of morphia was given at 6 A.M.

On August 1st, at 11 A.M., Dr. Wheeler found the patient looking better but complaining of great abdominal pain. The wound was dressed and looked well. The abdomen was very much distended and tympanitic. Half a grain of morphia with one-hundredth of a grain of atropine was given hypodermically. The patient passed a quiet day. Nutrient enemata were given at 12, 2, 4, and 8 P.M. The mouth was rinsed out occasionally with hot water. At 10 P.M. the patient was found to be in pain again, so the morphia and atropine injection was repeated. Nutrient enemata alternately with nutrient suppositories were continued every two hours during the night. On the 2nd the patient was found to have passed a fairly good night, but she still had a great deal of abdominal pain. Chloroform was administered and the wound was dressed, the gauze drain was removed, and the aperture in the wound was sutured with silk; the wound looked well but the abdomen was still tympanitic. On recovering from the anæsthetic the pain returned and the hypodermic injection of morphia and atropine was repeated. Nutrient enemata were continued as before and the mouth was rinsed with water. The hypodermic injection of morphia and atropine was repeated at 10 P.M. The patient passed a comfortable night during which she had two loose evacuations, passing the remains of the currant bun eaten on July 30th. On August 3rd a starch and opium enema was given at 11.30 A.M. to quiet the bowels. The patient was decidedly better; the pulse had fallen to 90 and the temperature to 100°. She passed a good day and sucked ice at intervals. Nutrient enemata were given as before. She had a morphia and atropine injection at 10 P.M. There were two more loose actions during the night; the starch and opium enema was repeated at 4 A.M. On the 4th she was very comfortable. Nutrient enemata and ice by the mouth were given as before. She had a morphia and atropine injection at 6 P.M. During the night she had six drachms of Valentine's meat

juice. On the 5th she seemed to be stronger: she had a teaspoonful of Valentine's meat juice and whey at intervals. The bowels were loose. Nutrient enemata were given as before. She had a morphia and atropine injection at 10 P.M. She passed a good night. Valentine's meat juice and whey (three drachms at a time) were taken by the mouth. She had nutrient enemata as before. On the 6th she was progressing most favourably; the abdominal pain and distension were much better. 11 ounces of fluid (Valentine's meat juice and peptonised milk) were taken during the day. She passed a good night but had slight bilious vomiting at 6 A.M. and 9 A.M. On the 7th she was given dilute hydrocyanic acid (three minims in half an ounce of water) every three hours. There was no more sickness. The patient's further progress was uninterrupted. The wound was dressed on the 8th and again on the 12th, when the stitches were removed, the wound having healed by first intention except at two points, where there were some small granulations. Solid food was given gradually with Benger's food and corn-flour, followed by fish and minced chicken. She got up on the 21st and left the hospital for a convalescent home on Sept. 20th with the wound soundly healed and feeling and looking better than she had done for months. During the last three weeks of her stay in the hospital she was taking five grains of citrate of iron and ammonium, ten grains of bicarbonate of sodium, and chloroform water to one ounce three times a day.

*Remarks by Dr. WHEELER.*—The operation for the relief of perforated gastric ulcer is yet sufficiently recent to justify, I think, the publication of this case. It presents also some unusual symptoms which appear to me to be worth recording. The non-obiteration of liver dulness and the moderate amount of shock led me at first to doubt whether I had to do with a case of perforation. The reason for this was evident when the abdomen was opened—there were no signs whatever of gas in the peritoneal cavity. The perforation must, I take it, have been very minute and possibly valvular, and being situated just under the liver was almost immediately inclosed by adhesions. The stomach, too, was most likely empty, as quite three hours had elapsed since food was taken; at the time of operation it certainly contained nothing but flatus. It was fortunate that the coats of the stomach afforded a good hold for the stitches; in a case which I saw in the practice of a colleague very great difficulty was experienced from this cause and they gave way after a few hours. The peritoneum was not flushed as I concluded that the amount of contamination was not great, and the intestines being so much distended a thorough flushing would have been a matter of great difficulty, but all the accessible parts of the cavity were carefully dried and freed from lymph. It only remains for me to express my thanks to my friend and colleague, Mr. L. W. Reynolds, for his valuable assistance at the operation, at which Mr. G. D. Bannerman and Mr. Turner were also present and rendered aid. To Mr. Cort my warm acknowledgments are due for his skillful administration of chloroform and for his assistance in the after-treatment of the case.

## Medical Societies.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

#### *Acute Dilatation of the Stomach.*

A MEETING of this society was held on Oct. 22nd, Dr. F. W. PAVY, the President, being in the chair.

Dr. H. CAMPBELL THOMSON read a paper on Acute Dilatation of the Stomach, with Illustrative Cases, which will be found printed in full at p. 1113 of this issue of THE LANCET.

Dr. T. R. BRADSHAW (Liverpool) thought that the most obvious explanation of these cases of acute dilatation was that they were due to obstruction at the pylorus. He failed to see how, if the dilatation were due to disturbance of the nervous mechanism, vomiting could occur, for without the active contraction of the walls of the stomach the fluid could not be expelled, and he also thought it probable that the fluid would escape through the pylorus unless there were obstruction. Another point again in favour of the view that there was obstruction at the pylorus was that in all the cases

mentioned in the paper the intestines below the pylorus had been collapsed. He mentioned the case of an elderly woman who on three different occasions had had attacks of sudden dilatation of the stomach, and in each of these relief had suddenly occurred. He attributed the sudden distension and rapid relief to a kink having taken place in the region of the pylorus.

Dr. W. P. HERRINGHAM criticised Dr. Thomson's explanation of the cause of the acute dilatation. He said he could understand paralysis of the muscular coats and the secretion of fluid which was unable to pass out distending the stomach, but he failed to see how the stomach would distend against the pressure of the abdominal walls unless there was some such agent at work. He pointed out that in all Dr. Thomson's cases the stomach was distended with gas, which must have been produced within the stomach, and this in association with the paralysis of the muscular walls was the cause of the dilatation.

Dr. ARTHUR VOELCKER said that the occurrence of dilatation of the stomach in conjunction with left-sided pleurisy accounted for certain physical signs which were often present—viz., the high level of the resonance which might occur at the base of the left lung. He thought that against the view that the condition was due to pyloric obstruction was the fact that bile had been present in the vomit of two of the patients. With regard to the treatment he hesitated to advise that the stomach should be washed out, especially in those cases in which the condition of the patient was critical.

The PRESIDENT said that he viewed the stomach in exactly the same way as any other hollow viscus, and as the bladder became dilated and lost its power of contraction when an obstruction interfered with the evacuation of its contents, so the stomach became dilated when the pylorus was obstructed. He agreed with a former speaker in believing that it was impossible for an active dilatation of the stomach to take place. Two conditions were necessary to give rise to the dilatation: the first was atony or paralysis of the walls of the stomach, and the second was the expansion of the organ by fluid or gas within it. He referred to certain experiments on dogs in which both vagi had been divided, and it was found that the lower end of the œsophagus was enormously distended with food which the dog had swallowed shortly before its death. In this case there was paralysis of the fibres of the œsophagus and dilatation by means of the food swallowed.

Dr. THOMSON, in reply, said he did not believe there was any obstruction at the pylorus, for no peristaltic contraction had been observed. He mentioned the heart as an instance of a hollow viscus dilating actively. He quite agreed with the President that the two factors he mentioned were necessary to produce the acute dilatation of the stomach.

## OPHTHALMOLOGICAL SOCIETY.

*Presidential Address: Some Clinical Experiences of Primary Chronic Glaucoma and the Value of Iridectomy.—Rodent Ulcer of the Cornea in a Child.—Exhibition of Cases.*

The first ordinary meeting of the session of this society was held on Oct. 17th, Dr. DAVID LITTLE, the President, being in the chair.

The PRESIDENT, after expressing his appreciation of the honour conferred upon him by election to the chair, proceeded to relate his Clinical Experiences of Primary Chronic Glaucoma and the Value of Iridectomy. He alluded to the unanimity of the profession in regard to the performance of iridectomy or sclerotomy well back in the corneal margin, as the only means by which hope of remedy was to be obtained, referring to the work of Brailey, Priestley Smith, Nettleship, and Collins in the pathology of glaucoma as substantiating this view. The series under review consisted of 40 cases in which he had made a long incision far back in the sclero-corneal junction, sometimes with and sometimes without removal of the iris. He considered that iridectomy was the more trustworthy procedure and he now adopted it as the primary operation, renewing the incision if subsequently necessary at the same spot. There was considerable difficulty in keeping patients under observation afterwards and the necessity for this in judging of the value of treatment was obvious. Among hospital cases from 1886 to 1894, excluding those in which the notes were imperfect, he found 67 miscellaneous instances of glaucoma; 11 patients had died, leaving 56, and of these 37 were traced. Ten—that is, close on one-fourth—had

become totally blind, eight from atrophy of the nerve without increase of tension and the other two from atrophy of the globe and recurrence of glaucoma respectively. Vision had deteriorated from atrophy of the nerve in four and the remaining 23 showed no great change. Some were a little better and others were a little worse than at the time of the operation, but for the most part they remained stationary—that is to say, 62 per cent. held their ground 13 years after operation. All except one preserved a normal tension and three maintained a low standard of vision, Jaeger—19 and 20, present before operation—practically hopeless cases. In advanced chronic glaucoma with marked reduction of vision the operation reduced tension permanently, but blindness was threatened in many by atrophy of the nerve. Few cases were traced after 12 years. Among cases in private practice three could be traced for a longer period. One man operated on 24 years ago (1877) at the age of 40 years still retained vision =  $\frac{1}{2}$  and normal tension in the right eye, the left having been lost through glaucoma four years earlier. In another the vision had been slowly contracting for three years. The disc was pale and excavated, but central vision =  $\frac{1}{2}$ . A third patient after 19 years preserved normal vision and tension. Eight others could see well after from 10 to 15 years. As regards acute glaucoma the President recalled one patient who lost one eye in 1870 and a week later suffered with this disease in the other; iridectomy was performed hurriedly at midnight and the eye was saved, normal vision being retained 27 years after. Three others were well after 20 years, and a fair number from 10 to 15 years after operation. For the most part sight remained stationary for some years and then failed in the periphery, the progress being gradual at first. Simple cases formed only a small proportion. The President regarded treatment by myotics as useless and recommended operation in all cases of simple glaucoma, early or late, if there was any vision left. In some the operation failed to check the progress of the disease; in others its development was retarded, even at the age of 70 years. Many failures could be traced to faulty operation; an incision too far forward was worse than useless. At all times the procedure was difficult and the greatest precision was needed. In the early stage pressure symptoms were often overlooked, but where the other eye had been lost they naturally frightened the patient, and such cases came under operation satisfactorily. In three such cases under the President's care obscuration occurred with tolerable frequency. The coloboma resulting from operation did not affect the acuity of vision or the power of accommodation. He did not advise operation for pains in the temples, but where one eye was already blind and the second was threatened by premonitory symptoms and obscuration, the operation should be performed at once. The premonitory stage was most favourable for iridectomy, as von Graefe taught. Eserine and pilocarpine might diminish the attacks and retard the disease, but did not effect any real cure and the disease eventually became acute or chronic. Cases operated on early showed no recurrence of symptoms or obscuration. The iridectomy then might be of moderate size and did not need to be so far back as in the more advanced cases; a keratome should be used and the attachment of the iris should be removed. In conclusion, the President said that there was too much blindness from glaucoma, which might be prevented if early operation was more general. Confidence in this proceeding was increasing rather than diminishing.—Mr. E. NETTLESHIP moved, and Mr. A. QUARRY SILCOCK seconded, a vote of thanks to the President for his address in a few appreciative words and this was accorded with acclamation.

Mr. S. JOHNSON TAYLOR read notes of a case of Rodent Ulcer of the Cornea in a Child, aged three years, who had been previously ailing for several weeks. The disease developed and extended during the last three weeks in March until the upper one-third of the cornea was involved by superficial ulceration, the free edge being grey and the sclerotic aspect vascular. There were at first lachrymation and photophobia, with hyperæmia of the lids. At this stage the ulcer was freely scraped and treated with liquid carbolic acid, a pad and bandage being subsequently applied. Quinine lotion, four grains to the ounce, was instilled. By the middle of April the ulcer had healed. This was an instance of Mooren's ulcer, the progress and cure being the more rapid, as it was extremely rare in a child. There was no hypopyon or perforation. It was not malignant and it represented a clinical entity due to a specific germ. As it traversed the cornea it

left a nebulous condition behind it.—Mr. G. LINDSAY JOHNSON referred to the greater frequency of this disease in carnivora and rodents.—Mr. NETTLESHIP remarked on the absence of relapse.

The following cases were shown:—

Mr. R. MARCUS GUNN: Persistent Double Keratitis, mainly Superficial, without Tendency to Ulceration.

Mr. LINDSAY JOHNSON: A case of Deep-seated, Infective Conjunctivitis of an unusual character.

Mr. SYDNEY STEPHENSON: A case of Congenital Distichiasis.

Mr. E. TREACHER COLLINS: A case in which Moore's Rodent Ulcer had six years previously involved the whole Surface of each Cornea.

Mr. N. BISHOP HARMAN: (1) Choroidal Angiosclerosis, with Pigmentary Degeneration (two cases); and (2) a case of Paresis of the Third Nerve in which on Lifting the Drooping Lid there was Coincident Drooping of the Sound Lid.

Mr. G. W. ROLL: Congenital Patch of Pigmentation in the Fundus Oculi.

Mr. L. V. CARGILL: Sclero-corneal Dermoids in Both Eyes.

Mr. SILCOCK: Primary Chancre of the Eyelid in an Infant.

## HARVEIAN SOCIETY OF LONDON.

### *Hæmaturia in Childhood.*

A MEETING of this society was held on Oct. 17th, Dr. D. B. LEES, the President, being in the chair.

Mr. CAMPBELL WILLIAMS read a short paper entitled *Hæmaturia in Childhood*. In many cases, owing to the obvious presence of disease with which hæmaturia was apt to be associated, the etiology, source, and prognosis could be fairly accurately given at once. In others, though the source of the hæmorrhage might be evident, the causation was obscure and judgment had to be withheld for at least a time. The various medical ailments, drugs, and parasites which gave rise to the condition were enumerated. The surgical aspect was next reviewed. Traumatism of the kidney, ureter, bladder, and generative organs was discussed. In connexion with laceration of the ureter mention was made of a case of hydronephrosis following the injury which necessitated nephrectomy. The effects of calculi in the various portions of the urinary tract were gone into. It was remarked that in many proved cases of vesical calculus in young children hæmaturia was absent and that the only diagnostic signs had been dysuria and infrequent micturition; also that frequency of urination was more common in infants when the stone was renally situated. The value of skiagraphy in these cases was pointed out. Tubercle of the bladder and kidney was dealt with and attention was drawn to the fact that the first noted symptom of renal tuberculosis might be copious hæmaturia. In connexion with phimosis as an exciting cause of vesical hæmorrhage Mr. Williams remarked that he had never met with hæmaturia due to phimosis uncomplicated with some other cause. Reference was made to sarcoma as the type of malignant disease which affected the urinary organs in infancy and childhood, but that the bladder was practically exempt from implication by it in the very early years of life. Also the fact was noted that, excluding sarcoma, the bladder was little liable to tumour formation. The rarity of papilloma, mucous polypi, and adenomata was pointed out. Caruncle of the urethra in female children was noted as an occasional cause of blood in the urine. Hæmaturia dependent upon scurvy rickets the result of improper feeding was discussed and attention was drawn to the fact that sometimes bleeding from the urinary organs might precede the usual osseous or oral manifestations of the disease. It was likewise pointed out that in hæmophilia hæmorrhage from the bladder or kidneys might constitute the primary declaration of this dyscrasia in a child.

Dr. SYDNEY PHILLIPS remarked that hæmaturia arising from tuberculous disease of the urinary organs, especially when the kidney was affected, might be very profuse. He had not seen hæmaturia in scarlet fever except as part of an acute nephritis. In a patient suffering from typhoid fever and scarlet fever at the same time fatal hæmaturia had occurred and was shown post mortem to have occurred from the bladder wall. In children it was not infrequent to find hæmaturia which seemed attributable to the mechanical action of oxalates or of uric acid found in the urine. He thought that hæmaturia and epistaxis might result from the rheumatic poison.

Mr. BUCKSTON BROWNE referred to the completeness of the paper and said that he could only think of one source of

hæmaturia in children which had not been mentioned—namely, the bursting into the bladder of an abscess connected either with the hip or the spine; and he instanced a case where he had removed part of the body of a vertebra from the bladder into which it had been discharged from a spinal abscess. He also mentioned a case of infantile hæmaturia seen with Sir Thomas Barlow where the cessation of the use of sterilised milk and the taking of a little orange juice were followed by excellent results.

Dr. G. A. SUTHERLAND agreed with Mr. Williams that hæmaturia did not occur in uncomplicated rickets. In scurvy hæmaturia might occur from renal or vesical hæmorrhage and was directly dependent on the general disease. In some cases, however, he thought that a local cause existed in the form of mechanical irritation of the kidneys by uric acid crystals. These were frequently passed in large amount in scurvy, as in most affections characterised by profound anæmia, so that if hæmaturia was the sole evidence of the hæmorrhagic tendency during an attack of scurvy it was advisable to examine the urine carefully for uric acid.

## LIVERPOOL MEDICAL INSTITUTION.

### *Opening Address of the Session by the President.*

The opening meeting of the session was held on Oct. 10th, when Mr. EDGAR A. BROWNE, the President, delivered the opening address, of which the following is an abstract.

After some prefatory remarks bearing on the work of the Institution the President said: To those who live in the midst of the most remarkable achievements of the intellect the conditions of mental progress must be a fascinating subject, from whatever side approached. Whether we give ourselves up to mere wonderment, or to a picturesque enumeration of recent triumphs; or whether we endeavour to analyse the causes, the evolution, and the development of modern ideas; whether we take a historical view of the past or endeavour to cast a horoscope of the future; whether regarded merely as an intellectual amusement or as a practical guide for the organisation of our medical schools, or even as a help for the improvement of our own minds, the interest of a general view of progress is likely to appeal to everybody. All travellers like occasionally to pause and to view the road they have traversed and to examine the map of where they are going. It would be wrong to take a survey of medical progress in a mere parochial spirit; our survey must be wide. We do not stand alone. There is no medical science, properly so-called; we are tied and bound by the condition of the collateral sciences on which we depend. We are opportunists, in the midst of our more precise brethren, taking from them what will serve our turn. But though we have no science we may claim a scientific method which in its way is exact and productive of good results. The art of the practitioner must be distinguished from his science; his knowledge of the details of other sciences from his appreciation of what his own science requires. If we could carry out to its logical conclusion the scheme of a modern preliminary examination—e.g., the matriculation of London—we should be, not physicians, but scientists. The more exact a science the less room for the exercise of art, and it is a union of the methods of scholarship and science with the personal skill in dealing with the half-seen and the obscure in clinical work that makes the practice of medicine so fascinating. But arts tend to be lost, and though science is more stable, not only sciences but civilisations themselves have disappeared. The Egyptians have gone. Their learning was sufficiently profound to command the respect of the Greeks, but it has vanished. The modern Greeks are a brave and intelligent people, but they have not a tincture of the old civilisation—theirs is French. The possibility that modern science may be destroyed must be admitted; therefore the mode in which the torch of learning is kept burning or becomes extinguished is full of interest. There is nothing to show that in historical times the individual brain-power has increased; the power of using it has. The increased power due to coöperation is enormous. We can only judge of the past by the remains of literature and architecture, and by those tests the ancient civilisations were raised by men fully our equals. The mental endowments of men have always been in three classes—men of genius, of talent, and the mediocrities. There is no sharp line of demarcation, as the characteristics may even be shown in the same individual under different circumstances. Genius can scarcely

be defined, as it is manifested in many various ways. In relation to science it means the possession of faculties especially adapted for the work to be done. A man of genius may be supposed to have a feline quality of vision, able to pierce the surrounding gloom of ignorance earlier than others; hence have sprung the ideas which lie at the foundation of progress. Genius, however, is not always of itself efficient, and the great value of the men of talent is as interpreters. They are capable of appreciating genius, of seizing the gist of new ideas, and of bringing them into touch with the knowledge of the times. The mediocrities of themselves do not appreciate genius, they like it diluted; they herd together, they have their shibboleths, they distrust originality, singularity, or independence of thought. Thus they maintain the atmosphere of any art or science they may be connected with. They profit most by education, and they serve the practical purpose of diffusing and applying the knowledge afforded them by the men of talent. Now, if we fail in educating the mediocrities sufficiently for them to appreciate the teaching of the more active minds the progress of knowledge is arrested, and science fails for want of diffusion. If genius fails on the other hand, there is little use for the man of talent, and under such conditions science may dwindle and even become lost. The inventive and research capacity of the Chinese must at one time have been considerable, but knowledge has not moved with them for 2000 years; they have settled down to a vast population of mediocrities occupied incessantly in passing examinations or examining others more mediocre than themselves. Appalling as the thought may seem, the possibility of the same thing occurring to ourselves, if our educational machinery becomes too complicated and tyrannical, is not wholly chimerical. Moreover, a great discovery may be made and become public, but from a want of sufficient collateral knowledge may not only fall flat and be useless, but may even become positively detrimental; take, for example, the familiar discovery of the circulation of the blood. There are various interesting points connected with the state of knowledge at the time it was made. Why was it not made before? First, it needed the establishment by Bacon, the protagonist of scientific thought in this country, of the inductive philosophy on the ruins of the ancient authority, especially that of Aristotle. Bacon found the physicians great offenders. He had a poor opinion of them; he said they reasoned in a circle, and doubtless he was right. But he gave them a serviceable map of the country. He said, "Look the facts in the face, form your own opinions, never mind the ancients." Until that method was accepted as the working method the passage of the blood through the arteries was not likely to be investigated, because the latter were supposed to be air-passages. A few advanced thinkers knew that some blood was mingled with the vital spirits, but no connexion with the veins was generally accepted. The liver, not the heart, was the prime motor, and when a thing was believed and was obvious on superficial examination it took an original mind to look below the surface. Then it was a very unmechanical age. People did not concern themselves with the body as a machine—it was a vital organism and a marvel, and not to be too rudely examined either. Then the collateral sciences were not ready. Oxygen was not discovered for more than 150 years. Before oxygen was discovered the knowledge of the mere paths of the circulation was no good, so instead of seeing that the central fact about the circulation was its connexion with respiration, and accounting tentatively for the existence of the pulmonary tract, attention was merely confined to the movement of the blood—the movement and not the reason for the movement—and therefore they bled. Thus, the value of a great discovery was not only negated but perverted.

The address, which was listened to with great attention and was delivered without the assistance of any notes, ended somewhat abruptly owing to want of time.

**SOCIETY FOR THE STUDY OF INEBRIETY.**—A quarterly meeting of this society was held on Oct. 8th in the rooms of the Medical Society of London, Chandos-street, Cavendish-square, London, W., Dr. Wynn Westcott, coroner for North-East London, being in the chair.—Dr. Martyn Westcott read a paper on Sea Voyages in the Treatment of Inebriety. He said that although he could not boast of a very long experience of life at sea, yet he had formed a decided opinion about the suitability of sea voyages as remedies for drunkenness. In the case of the chronic drunkards who

might be considered hopeless, it was generally found that they suffered from fatty heart and fatty or cirrhotic liver or kidney disease. Not only were these patients disinclined to mend their drinking habits, but they were physically run down and debilitated, and therefore needed nursing and supervision. Life on board ship under the most favourable circumstances was not all comfort and rest, and the nursing, dieting, and quietude so essential for such invalids were very seldom to be obtained. Few cases of advanced disease of any type seemed to him (Dr. M. Westcott) fit for sea-life even at its best. There were also the habitual drunkards and the dipsomaniacs who indulged only in periodical bouts. A few months, or even years, spent in the healthy atmosphere of a home for inebriates, where discipline and dieting were carried out under medical supervision, would do much towards restoring the drunkard's self-respect and strengthening his good resolutions. Then before resuming business a sea voyage might be undertaken. The ideal sea voyage for these patients was one taken in a sailing-ship which was commissioned on teetotal principles, with a teetotal captain and crew, and which touched at scarcely a single port *en route*, but no reformed drunkard should be trusted on a sea voyage *alone*. There was no doubt whatever that the idleness and monotony of the life and the saltiness and the moisture of the air would tend to produce thirstiness. He did not consider a sea voyage in the light of a remedy where dipsomaniacs were concerned. It was usual for people to drink a good deal just before reaching the "home" port, and no doubt this was because they were in a disturbed, excitable state, expecting reunion with their friends, a return to the "old country," and a feeling that they ought to do something unusual. The periods of nervous irritability, depression, and præcordial distress to which the dipsomaniac was subject were likely to be more frequent on board ship than ashore. Therefore, if a dipsomaniac really wanted to be cured he (Dr. M. Westcott) would discourage him from embarking on a sea voyage. On the other hand, if any drunkard were really reformed and so sure of himself as to be proud of being a total abstainer there was no doubt that he would derive considerable benefit in his general health from the fresh outdoor life and change of surroundings characteristic of a sea voyage.—A discussion followed.

**MANCHESTER CLINICAL SOCIETY.**—The first meeting of the seventeenth session of this society was held on Oct. 14th at the Palatine Hotel, Mr. Herbert Lund, the President, being in the chair.—The President, in his introductory address, entitled, "Along the Urinary Tract," related numerous cases of surgical interest which had occurred in his practice. The liability to overlook the presence of vesical calculus in children suffering from phimosis and the tendency to neglect the "lacuna magna" in cases of recurrent gonorrhœa which resisted the ordinary treatment by injections were referred to and examples were cited. Suprapubic cystotomy in preference to lithotomy in patients the subjects of vesical calculus in whom the prostate was enlarged was strongly recommended, and the danger of getting a troublesome urinary fistula from the retention of a drainage-tube for any lengthened period was clearly demonstrated. That the bladder might be the seat of tertiary syphilitic ulceration was shown by two cases, in one of which the bladder had been opened for supposed malignant disease, and a large ulcerated surface was found. Under specific treatment the patient made a good recovery. Other cases of interest in renal surgery concluded the address, for which a hearty vote of thanks, moved by Dr. Holgate Owen and seconded by Mr. Stanmore Bishop, was accorded to Mr. Lund.—The following is the list of office-bearers for 1901-1902:—President: Mr. Herbert Lund. Vice-Presidents: Dr. E. T. Milner and Mr. J. E. Platt. Honorary treasurer: Mr. C. F. H. Kitchen. Honorary librarian: Dr. J. W. Hamill. Committee: Mr. Samuel Bagley, Mr. G. H. Broadbent, Dr. A. Brown, Dr. J. Gray Clegg, Dr. J. W. Crawshaw, Dr. J. Daniel, Dr. W. E. Fothergill, Dr. A. B. Fulton, Dr. James Holmes, Dr. D. Macmillan, Dr. F. Craven Moore, Mr. David Owen, Dr. R. T. Parkinson, Dr. E. J. Walker, and Mr. F. H. Westmacott. Honorary auditors: Dr. Alex. Fraser and Dr. W. K. Walls. Honorary secretary: Mr. J. Howson Ray.

**IPSWICH CLINICAL SOCIETY.**—A meeting of this society was held at the East Suffolk Hospital on Oct. 10th, Mr. J. F. C. Hossack being in the chair.—Dr. G. Vincent showed a patient who was suffering from Intractable Veldt

Sores. He had served in South Africa. No treatment appeared to have any effect.—Mr. Bartlet showed: (1) A case of Gunshot Wound of the Arm; and (2) a case of Sarcoma of the Mamma.—Mr. A. Y. Pringle showed a case of Carcinoma of the Mamma with Secondary Growths in the Liver.—Dr. H. H. Brown showed two specimens of Uteri removed for Carcinoma. He read notes on these cases. He also showed a specimen of Paget's Disease of the Nipple which he had removed; he commented upon the rarity of the disease.—Mr. C. K. Mosely showed a specimen of a Child's Larynx and Trachea with a penny firmly embedded at the bifurcation of the bronchi. The history was as follows. The child was brought to him six years ago with the history that she had swallowed a penny. No penny could be seen or felt and a skiagraph also gave no result. The child was comparatively well, with occasional asthmatic attacks, some bronchitis, and on one occasion pain under the right arm. She suddenly had an attack of profuse hæmorrhage from the mouth due to the ulceration into a blood-vessel and died.—Dr. W. W. Sinclair read a very interesting paper upon Local Anæsthetics. He deplored the fact that general practitioners did not make enough use of these useful drugs. He read notes on several cases. Among these he mentioned one of an old man who was in too weak a state to stand a general anæsthetic. He enucleated one eye with beta-cocaine and cocaine. He found beta-cocaine a most useful drug with practically none of the drawbacks of ordinary cocaine.—A long discussion ensued in which several members took part.—It was unanimously resolved that the honorary secretary, Dr. W. A. Gibb, should be asked to take charge of the Pathological Museum.

**BRISTOL MEDICO-CHIRURGICAL SOCIETY.**—The annual meeting of this society was held in the Medical Library of University College, Bristol, on Oct. 9th, Dr. D. S. Davies (and afterwards Dr. Barclay J. Baron) being in the chair.—Dr. Baron gave his presidential address on the Progress in the Diagnosis and Treatment of Disease of the Throat, Nose, and Ear during the past 20 Years. He drew largely from the lessons that his experience of special professional work had taught him, and he showed that the progress that had taken place in the knowledge of general medicine and surgery had been fully shared by this special branch.—The reports of the honorary secretary (Mr. J. Paul Bush), the editorial secretary (Mr. J. Taylor), and the honorary librarian (Mr. L. M. Griffiths) were read and adopted.—Mr. G. Munro Smith was elected President-elect and Mr. Paul Bush honorary secretary. The following six members of committee were elected: Dr. J. Michell Clarke, Dr. B. Rogers, Dr. H. Waldo, Mr. J. Dacre, Mr. J. Taylor, and Dr. P. Watson Williams. The following were elected to serve on the Library Committee: Mr. L. M. Griffiths, Mr. G. Munro Smith, and Mr. J. Taylor.
